Is there any reason why the anterior ethmoidal veins should be specially liable to bleed? Their position certainly does not explain the tendency. They are situated in the most secluded and best protected part of the nasal cavity, and the tissues covering the septum do not yield less support in this region than elsewhere. In size they are by no means the most important in the nose. Although the naso-palatine is larger and follows a longer and more exposed course over the septum bleeding evidently takes place from it very rarely. Natier,[3] however, reports a case of hæmorrhage from the naso-palatine artery. A feature, however, that distinguishes the anterior ethmoidal veins from the other veins of the nose is their close connexion with the intracranial circulation. Herein lies, in my opinion, the explanation of the profuse and prolonged epistaxis in the cases above reported. The ethmoidal veins anastomose with the veins of the dura mater and with the superior longitudinal sinus. Another and more important vein, which has been specially described by Zuckerkandl,[4] accompanies a branch of the anterior ethmoidal artery, passes through the cribriform plate into the cranial cavity, and either opens into the venous plexus of the olfactory tract or is directly connected with a larger vein at the orbital lobe. The chief trunk of this vein has also been seen opening into the superior longitudinal sinus. The fact that these veins can be injected from the longitudinal sinus proves the absence of valvular obstruction to a backward flow. This condition and the pressure in the sinus, which has been shown by Hill[5] to follow closely the general circulatory pressures, would allow of abundant hæmorrhage from the proximal end of a ruptured ethmoidal vein. The other emissary veins are usually so small in the adult as to preclude serious hæmorrhage, and comparisons cannot be drawn between them and the ethmoidal veins. In the young, however, they may be of importance. Thus, in removing a cerebellar tumour from a child Parry[6] opened a large vein which communicated with one of the sinuses in the skull and great loss of blood resulted.

The connexion between the nasal veins and the intracranial veins referred to has received little or no attention from anatomists with the exception of Zuckerkandl. It is not astonishing, therefore, that these veins have escaped the notice of the rhinologist and that in an extensive search through the literature of the subject I have found no allusion to them as a possible source of epistaxis. Nevertheless it is from these vessels or from some anastomosing with them that one would expect the bleeding which is followed by a sense of relief in the head.

Epistaxis from the region of the anterior ethmoidal vessels is easily checked by firmly packing between the septum and the anterior half of the middle turbinate a strip of gauze reaching to the roof of the nose or as near to it as possible. The parts below may be left free so that nasal respiration is unimpeded. This is a great advantage over the method generally recommended, of plugging anteriorly, or anteriorly and posteriorly, which causes almost intolerable discomfort to some patients. After the packing has been changed twice or thrice at intervals of a day, or, if it can be introduced without becoming saturated with blood, of two days, the tendency to bleed will usually have ceased and the treatment may be suspended.

Glasgow.

CASE OF

MEASLES IN A PATIENT AGED 18 YEARS COMPLICATED WITH MENINGITIS AND SPINAL MYELITIS; RECOVERY

By E. F. ELIOT, F R C S, L R C P, EDIN,
F F P S GLASG, &c.

DURING the last week of April, 1898, I was called upon to attend a finely grown, well developed girl 18 years of age who had been exposed to the infection of measles, and, as was anticipated, she developed a rash on May 1st Everything was perfectly normal and the rash was well developed over the face and the whole surface of the body On the 4th (the fourth day of rash) I saw her at 11 A M, and she was doing perfectly well and had had a good night About 3 P M she became restless and commenced "to grind her teeth," which continued till 6 P M when she was suddenly seized with a convulsive attack, described by the nurse as "epileptiform in character." There was no clonic spasm and the limbs were rigid and without motion Warm milk was swallowed whilst the patient was livid. The aperient medicine given on the night before had not operated, a glycerine enema was therefore given and whilst this was acting a second attack took place During this attack the face became livid (purplish) and there were random movements of the arms and the legs I saw her as she was recovering from this attack, which lasted for 10 minutes She was evidently much shaken by it The pulse was rapid and very feeble and she was "muttering" and "grinding her teeth." The temperature was 101 2° F I gave her two drachms of brandy and eight grains of bromide of potassium She remained fairly quiet for about an hour and during this time she was seen by Dr T W Trend The pulse had improved and the patient was in a profuse perspiration The heart sounds were normal but the breath sounds were somewhat harsh at the right apex She understood what was said to her At the end of an hour a third attack came on quite suddenly This lasted for two minutes It was epileptiform in character, the patient uttering a faint cry, her face and hands being livid and her whole body convulsed After the acute stage had passed off she continued to move her arms and legs, to grind her teeth, and to mutter for about 20 minutes Then a fourth attack came on, similar to the third, but only lasting for about a minute After this attack there was very little random movement Brandy and bromide and milk and soda-water were administered after each attack During the third and fourth attacks she passed flatus and fæces unconsciously For six hours after the fourth attack she steadily improved Her voice was strong, she had twitchings of the mouth but no grinding of the teeth, and she was quite conscious At 4 A M she was lifted out of bed and she passed a fair quantity of urine of a specific gravity of 1020 with no albumin The reaction was acid The temperature after the fourth attack was 103 2°, and at 4 A M it was 101 8°, the pulse being 98 I may add that the menstrual period was due on the 4th, but it appeared only slightly for a few hours on the 3rd Her mother informed me that the period usually was six or seven days behind time

My opinion at this time as to the cause of the convulsions was that they arose (1) from toxic poisoning from measles, (2) from cessation of the menstrual period, and (3) from the patient being in a somewhat neurotic condition

On May 5th I saw the patient again with Dr Trend Her temperature was then 100 6° and the pulse was 98 She was awake and quite sensible and was breathing well The heart sounds were good She had been quiet and sleeping for short intervals During the day the patient was very quiet and she took medicine and nourishment well I prescribed bromide in an effervescing mixture and brandy, milk, and barley water On the 6th the patient was very restless up to 2 A M, but afterwards she slept at intervals She passed urine twice in the night and at 4 A M her bowels acted At 7 A M she began to twitch her mouth and occasionally to grind her teeth, and at 8 A M I ordered a full dose of bromide She was perfectly conscious, her mind was quite clear, and she answered questions readily At 9 A M the temperature was 97 2° and the pulse was 80 There was a slight cough at times and her arms and legs twitched in her sleep, as did her mouth when she was awake I saw her with Dr Trend and we agreed that she was going on well An enema was ordered On the 7th we found that she had had a fairly good night and that there was nothing of importance to note We prescribed three grains of subchloride of mercury The pulse was low and depressed She had a quiet night on the 8th and her condition was much the same The percussion note was slightly dull over the right base at the back, but there were no râles or tubular breathing The patient appeared to be progressing on the 9th, with no fresh symptoms On the 10th she became very drowsy during the night and slept heavily There was more dulness over each base at the back The heart's action was feebler, but the sounds were clear We did not consider her condition satisfactory, and Dr Hughlings Jackson was asked to see the patient and he arrived at 6 P M. The treatment at this time was as follows The room was kept dark and cool We ordered her position in bed to be changed and her shoulders to be more raised Brandy, champagne, beef juice, and Benger's food were directed to be given, and subchloride of mercury and Rubinat water as necessary A mustard plaster was applied to the nape of the neck and cold to the head. Salines, digitalis, bromide, ether, &c, were also ordered Dr Hughlings Jackson (May 10th) reported that this was a very uncommon and difficult case The condition might have been due to "measles process" or to a simple meningitis from the first The treatment was to "keep her going," and it was just possible, even if there was meningitis, for a recovery to take place There was no pain or tenderness over the mastoid Examination of the eyes —After application of cocaine nothing abnormal was found in the discs; the pupils were equal and slowly reacted to light A bright light did not seem to annoy the patient Examination of the chest —The respiration was markedly abdominal; a percussion note was clear all over the chest; there were some few râles over both bases behind; and the respirations were 30 a minute The heart sounds were clear and normal The pulse was good and steady (80 per minute) The abdominal viscera were apparently healthy. The specific gravity of the urine was 1025, there was no albumin and but little phosphates. There was absence of patellar reflexes and ankle clonus. None of the symptoms were considered to be due to any neurotic element

On May 11th, since 6 P M on the previous evening the patient had been quiet and sleeping There was no twitching The urine and the fæces were passing involuntarily At times the patient roused up and answered questions The rigidity of the muscles of the neck was more marked, but the general symptoms were much the same At 5 P M I saw the patient in consultation with Dr Mitchell Bruce, who gave his opinion that there was nothing functional in the case, and that it was probably a local, non purulent, inflammatory meningitis, plus spinal myelitis, and that the question of thrombosis of the longitudinal sinus ought to be kept in mind He thought that the condition was a most rare and grave one, but that there was a possibility of recovery The treatment adopted now was as follows The room was directed to be kept cool and dark, the head and shoulders of the patient to be raised and the position of the body to be changed from side to side Eight minims of tincture of nux vomica every four hours and three grains of subchloride of mercury every second or third day were ordered, with brandy, champagne, and beef tea Mustard plasters to the nape of the neck from time to time were also ordered

On May 12th the patient had had a good night During the night there had been two marked periods of consciousness, the patient talking quite rationally At noon the temperature began to go up and during the afternoon she was evidently not so well The temperature continued to rise and the pulse became very rapid and weak Drowsiness was increasing and there was difficulty in swallowing At 9 P M she was much worse Her temperature was 103 2°, her pulse was 150 and she was breathing very badly. I ordered ice to be applied to her head and her hair to be cut off Digitalis and ether mixture, a nutrient and stimulant enema and general sponging with mustard were also ordered This treatment was continued through the night of the 13th The patient two or three times became almost pulseless but about 7 A M she rallied The temperature was 101° and the pulse was 120 She recognised her father. The ice, digitalis, and ether were continued. At 12 noon the patient had another very bad attack and a fatal result was expected, the temperature rising; but during the afternoon and evening she rallied and had several slightly lucid intervals. On the 14th she had had a much better night with fairly quiet sleep and nourishment was taken. The pupils slightly responded to light, which they had failed to do on the night of the 11th. During the last three days I had noticed that the temperature went up before the bowels acted and came down after the bowels had been relieved. During the next two days her condition was much the same. The attacks of coma were not so severe, and she took nourishment well. On the 17th her condition was much the same. The bowels were kept acting freely. The patient could talk and answer questions in a whisper. The limbs were absolutely rigid and the toes were extended. The patient now complained of pain in both legs. The legs were gently rubbed for the first time. There were no patellar reflexes or ankle clonus. She was able to move her arms a little better, and the muscles of the neck were a little less rigid. She could also move her head a little. The pupils responded sluggishly to light. The muscles of the lower limbs had only wasted a little, and there was no marked emaciation. On the 18th the patient had had a good night. The temperature varied from 100° to 100·6° and the pulse from 100 to 110. The plantar reflexes were slightly present and she could just move her toes. The pupil reflexes were not so good. The general condition was much the same. On the 19th the general condition was not so good, the patient seeming to be generally weaker. The symptoms were the same as on the previous day. At the middle of the day I decided to give her iodide of potassium and solution of perchloride of mercury, alternating with quinine, iron, and digitalis. During the day the patient was very drowsy. The temperature rose to 102° and the pulse became very rapid. Some cough developed during the day. The quantity of nourishment was increased. At 9 P.M. her condition was bad and I had her spine packed in ice. After ice had been applied she gradually improved and had had a fairly good night on the 20th. She complained during the night of pain in both legs. Ice was constantly applied and her temperature at 7 A.M. was 97·2°, the pulse being 80 and respiration good. At 7.30 A.M. the ice was removed from the spine. During the night the patient had expressed a desire to have the bowels opened, and at 12 noon they acted. At 5.15 P.M. she passed urine consciously, and at 6.30 P.M. the bowels acted well. During the day ice was applied at intervals to the lumbar spine.

On May 21st the patient passed a fairly good night. The nurse informed me that she had been more conscious on passing fæces but had taken no notice on passing urine. At 11.30 P.M. she asked for the bed-pan and used it, but urine passed involuntarily all day. On the next day there was no change, but at 8 P.M. the temperature rose to 101°; ice was immediately applied to the back. Her condition on the 23rd was much the same. She had not had a good night, but when she was washed in the morning she was able to bend her knees very slightly. It was noticed that during the previous three or four days the patient had decidedly lost flesh. During the night and the day she had a troublesome cough. The temperature was 100°. There was no material change in her state on the next day. On the 25th she had passed a good night and could move her right leg slightly, but not the left. Her intellect seemed clearer. She passed a good night on the 26th taking nourishment freely. Her legs were rubbed twice a day. I saw Dr. Mitchell Bruce in London and discussed the case with him; we were of opinion that it was now one of myelitis of the dorsal region of the cord. It was, therefore, decided to increase the iodide and the solution of perchloride of mercury and to continue the massage. On the 27th more movement in the lower limbs was noted. It was very slow but there was no pain. For the next three days the patient generally improved. On the 31st she commenced taking solid food. On June 1st slight patellar reflexes were found to be present for the first time, and there was more power generally. The next day the improvement was marked and the sensation in the limbs was normal. The patellar reflexes had slowly improved on the 6th. On the 11th she had a sleepless night and

except one drachm of syrup of iodide of iron. The menstrual period came on on the 22nd. The patient's sight was distinctly affected, there being short sight for all small objects, also red to green colour-blindness. Most greens looked at first—i.e., two weeks previously, when this condition was first noticed—orange; they now looked greener. Red and purples appeared as sage-green, green, or shades of mauve. She went out for a drive and she had been in the garden for the last 10 days. On Sept. 1st I learned that she had been away to the seaside. The patient was now perfectl well in every respect.

This case appears to me to be one of peculiar interest, although spinal cord lesions occurring in the exanthus sta of measles are recorded they are nevertheless somewhat rare, and in a number of cases they have proved rapidly fatal. A case is recorded by Barlow[1] which presented a somewhat similar train of symptoms. In Barlow's case death occurred on the eleventh day. A detailed account of the post-mortem and microscopical appearances of the spinal cord are given at length and are most interesting. In my own case I would suggest that the changes in the cord were vascular in character and of greatest intensity in the dorsal region. Probably the vessels were surrounded by a zone of coagulated exudation and the neighbouring tissues were infiltrated with leucocytes. It is impossible to say whether there were any interstitial hæmorrhages. I think there can be no doubt that the bladder symptoms, the paralysis of the lower limbs, the degree of paresis which existed in the upper limbs, and the absence of knee-jerks and of plantar reflexes, were all spinal symptoms. The question is, What was the relation between the myelitis and the measles? This patient was absolutely well before she sickened for measles. She contracted measles from a relative (who sat next to her at lunch and who developed a profuse rash on the next day). The incubation period was normal and a few days afterwards she had symptoms of meningitis, followed by symptoms of myelitis. I think that there are a sufficient number of cases on record to show that there is a distinct relation between measles and a form of myelitis which may be produced by the virus concerned in the other phenomena of measles.

I am very glad that I was able to have the opinions of Dr. Hughlings Jackson and Dr. Mitchell Bruce. At the time when they saw the case it was impossible to form an other opinion than that death must very shortly take place The result of this case teaches us how in an apparentl obviously hopeless condition a victory may be gaine Except for the incessant watching on the part of the nurs the patient would have died. On several occasions the pu was uncountable and scarcely perceptible and I har thought that death could be warded off. It was interest to note the comparatively rapid recovery, and I am sure t the iodide of potassium and solution of perchloride mercury were of great use.

I have published this case as it may be of intere practitioners, and it is comforting to know how absol complete recovery can occur in cases of this sort. greatly indebted to my partner, Mr. R. F. Chance, fo valuable aid and assistance during this very trying case

Southampton.

AN ANOMALOUS CASE OF CONTIN FEVER WITH ABSCESSES OF TH LIVER.

By J. G. McNAUGHT, M.A., M.D. GLASG
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

THE following case may be of interest in conne that reported in THE LANCET of July 30th, 1898 (by Dr. Sidney Herbert Snell.

A gunner in the Royal Artillery, aged 24 admitted to the special wards of the Statio Quetta, on Jan. 9th, 1898. For some time h suffering from intermittent fever, apparently origin. For two days at least before admissio been continuous. His temperature on ad 102·6° F. His face was flushed and his tongue furred. There was no abdominal distension had three or four loose motions daily. The spleen was slightly enlarged; the heart and lungs appeared to be normal. On Jan. 12th his temperature was 100·4° in the morning and 105° in the evening; on the 13th it was 100·4° in the morning and 101·6° in the evening. On the 14th he complained of severe pain in the right side, aggravated by movement and by taking a deep breath. A friction rub was heard at the inferior angle of the right scapula on auscultation. There was no dulness on percussing the base of the lung. The lower border of the liver was tender on palpation. On the previous day he had had six loose, light yellow motions. On this date he passed about one ounce of bright blood from the bowel. The tongue was dry and brown in the centre. His blood gave incomplete reaction to Widal's test; distinct clumping occurred, but many bacilli remained actively motile at the end of half an hour. His temperature was 101·2° in the morning and 100° in the evening. On the 15th he seemed much better; the pain in the side was relieved, there was no diarrhœa, and the tongue was cleaner and moist. His temperature was 102·2° in the morning and 103·8° in the evening. On the 16th there was a second hæmorrhage from the bowel, about five ounces of bright blood being passed. There was still pain in the right side on coughing, the respiratory murmur was very feeble, and the percussion note over the extreme base posteriorly was dull. The facies was now very suggestive of enteric fever, the tongue was brown and dry in the centre, and red at the tip and edges. The abdomen was somewhat distended. There were no rose spots. The blood gave a marked but incomplete reaction to Widal's test. The blood was examined for malarial parasites, but only one degenerated pigmented spherical body was found. His temperature was 100° in the morning and 102° in the evening. On the 17th he was restless and had passed a bad night. His temperature was 101·6° in the morning and 103° in the evening. His pulse was 140 and his respirations were 48 per minute. His pulse was very weak; his tongue was brown in the centre, furred at the sides, and red at the tip and edges; his abdomen was more distended and there were no rose spots; a small motion was passed containing some dark altered blood and some bright blood. On the 18th his condition improved; his temperature was 100·4° in the morning and 104·6° in the evening. On the 19th he complained of abdominal pain and was perceptibly weaker; one motion was passed containing altered blood; his temperature was 100° in the morning and 102·6° in the evening. On the 20th his condition was somewhat better. He passed two fluid, light yellow motions without any blood in either. The lung condition remained unchanged. His temperature was 100° in the morning and 103° in the evening. On the 21st the blood was again subjected to Widal's test and gave an incomplete reaction. His temperature was 99·6° in the morning and 102·8° in the evening. On the 22nd his temperature was 99·4° in the morning and 101·6° in the evening. He continued to do fairly well till the 23rd when he became very restless and had two large hæmorrhages from the bowel. A swelling was noticed in the epigastrium; it was dull to percussion and no fluctuation was detected. The urine contained bile pigment. In the evening he had two large hæmorrhages and became collapsed; the pulse was fluttering and very weak and the extremities were cold, but he rallied under treatment. His temperature was 98·4° in the morning and 100° in the evening. On the 24th he had a number of hæmorrhages from the bowel and became again collapsed, but rallied under treatment by opium and champagne. His temperature was 97° in the morning and 96·4° in the evening. On the 25th he passed a large number of small "tarry" motions involuntarily; the pulse became imperceptible and the respirations shallow and sighing, and he died quietly about 10 A.M. His temperature that morning was 96°.

---

[1] Transactions of the Royal Medical and Chirurgical
p. 77.

Necropsy.—The right lung weighed 16 ounces; its substance was very anæmic. It was adherent at the base to the chest wall and diaphragm. A small portion of the base was consolidated, dark-red in colour, and leathery in consistence. The left lung weighed nine ounces and was very anæmic; it was slightly adherent at the base. The heart weighed 10 ounces; the walls of the right ventricle were thin, pale, and extensively infiltrated with fat. The liver was much enlarged, especially the left lobe, and weighed 84 ounces. It contained five abscesses, three in the right lobe and two in the left. Two of the abscesses were as large as turkey's eggs; the others were smaller. One of the abscess cavities contained bile, the others contained thin yellow pus. The liver was adherent to the diaphragm. The spleen weighed eight ounces. The kidneys were very anæmic. The stomach and small intestine showed no abnormal appearances. Close to the ileo-cæcal valve and on it were a number of irregularly shaped ulcers, some of which were two-thirds of an inch long and others smaller. The mucous membrane of the two feet of the large intestine next the valve was congested and contained numerous ulcers, the largest being nearest the valve. Beyond a distance of six inches from the valve the ulcers were small, circular, and punched out in appearance. The mucous membrane of the remainder of the large intestine and rectum was quite healthy. There was no thickening of the walls of the bowel at any point. The mesenteric glands were swollen and soft.

The spleen was incised with a sterile knife and three tubes of Parietti's broth were inoculated from it. In all three tubes there grew a bacillus and a coccus, the bacteriological examination of which gave the following results. (*a*) The bacillus in Parietti broth produced a slight turbidity in 48 hours and a marked turbidity in 72 hours (at 90° F.). In broth it produced turbidity in 24 hours; after a week's incubation at 90° F. a pellicle formed. In gelatin-stab cultures there was a growth visible in 48 hours; there was a greyish-white slow growth on the surface and a beaded growth in the substance of the gelatin. In gelatin-streak cultures there was growth visible in 48 hours—slow growth, bluish white, irregular edges; there was no liquefaction. In glucose-gelatin shake culture there was turbidity in 24 hours, with slight gas formation in from three to eight days. Sterilised milk did not coagulate in 10 days. On potato there was moist transparent growth in 24 hours (at 90° F.); in a week the growth became thick and greyish. Agar streak culture gave a thick creamy-white growth. Gelatin plate culture gave a slow growth in 72 hours; the colonies were granular and dark in the centre; there was no liquefaction. The microscopic characters of the organism were as follows: a short, thick, sluggishly motile bacillus with rounded ends. Stained by dilute carbol-fuchsin some bacilli showed slightly stained central portions and deeply stained ends. Long thread-like forms were also seen. (*b*) The coccus appeared to be streptococcus pyogenes from its cultivation characters.

The clinical characters of the case were at first puzzling, but latterly they were quite consistent with a diagnosis of enteric fever. Neither the clinical history nor the post-mortem appearance supported a diagnosis of dysentery. I inspected the motions regularly and they never presented any dysenteric characters. The bacillus isolated from the spleen resembled bacillus coli in most of its characters, but it did not coagulate milk, it only produced gas after from three to eight days' growth in glucose-gelatin, and at first the growth on potato resembled that of bacillus typhosus.

TWO CASES OF PULSUS PARADOXUS.

BY JOHN HAY, M.B. VICT.,
ASSISTANT MEDICAL OFFICER, MILL-ROAD INFIRMARY, LIVERPOOL.

UNDER certain conditions the pulse becomes distinctly smaller during inspiration or completely disappears and this form of pulse is named the "pulsus paradoxus." It is not of common occurrence, though probably not so rare as is usually supposed, often being looked upon simply as an irregularity of the pulse whilst the rhythmical character of the irregularity is not perceived. This condition is usually bilateral but is occasionally not so, an interesting case of this nature being recorded by Dr. Thomas Harris of Manchester in THE LANCET of April 22nd, 1899, p. 1072.

As to the value of the sign, opinions differ greatly, but I think that we may take it that pulsus paradoxus is not *of itself* pathognomonic of any condition, though it cannot be denied that it does exist in perhaps its most marked form in certain cases of indurative anterior mediastino-pericarditis; but there are other conditions in which it is sometimes present, such as pericarditis with effusion uncomplicated by mediastinitis, also in pleuritic effusion and in patients suffering from great inspiratory dyspnœa.

The following two cases illustrate to some extent (1) these three conditions as causative agents; (2) the relief

rapid and uninterrupted, there being no repetition of the abnormal pulse condition.

Here I think the dyspnœa was the active cause, but so long as the arterial tension remained fairly good no paradoxical pulse showed itself; however, on the occasion of the tension dropping and the pulse becoming soft, then the dyspnœa was able to produce a definite effect, the result being the pulsus paradoxus

CASE 2.—A man, aged 40 years, was admitted into hospital on Feb. 8th, 1899, suffering from broncho-pneumonia complicated by pericarditis with effusion. He had been ill for four days previously to admission. His condition was critical and he had an irregular temperature ranging between 99° and 104° F. The pulse-rate was 130 and the respirations were from 40 to 60 per minute. Under treatment he improved considerably up to Feb. 21st. From that date he slowly began to lose ground, his most prominent symptoms being marked restlessness, a very troublesome cough, considerable dyspnœa, and inability to sleep in the recumbent posture; towards the end he became delirious. His temperature remained a little above normal, the dyspnœa increased, and he died suddenly on March 26th. The definite improvement in the general condition up to Feb. 21st was associated with the gradual clearing up in the lungs. Following this, however, the pericardial condition and the cardiac changes accompanying it became the main factors in the case and were the direct cause of death. On March 13th I made the following note: "The patient is still suffering greatly from dyspnœa, cannot lie down, and is occasionally attacked by great difficulty of breathing, the number of respirations increasing to 70 per minute. During these attacks he becomes almost frantic. They are not associated with marked cyanosis The præcordial dulness is increased in area, extending two inches to the right and five and three-quarter inches to the left of the middle line, together making a transverse dulness of seven and three-quarter inches. There is dulness in the first left interspace extending one and three-quarter inches from the middle line. No friction rub is to be felt on placing the hand over the præcordium, and only an indefinite cardiac pulsation. The apex beat cannot be seen or felt, and the heart sounds are practically inaudible. There is occasionally a short systolic murmur in the fourth and fifth spaces. There are râles to be heard in the chest, more particularly over the lower lobes, and a pleural friction rub over the right middle and lower lobes. There are definite signs of fluid at the right base, the dulness reaching as high as the ninth spine. The liver is eight and a quarter inches in nipple line and is enlarged and tender The spleen measures four inches in long diameter. The veins of the neck and arms are tense and engorged, but there is no definite cyanosis." The left pupil was dilated and larger than the right, a condition which I have noticed in several cases of acute pericarditis with effusion. His radial pulse was soft, frequent, and varied rhythmically with the respiration.

Tracings Nos. 4, 5, 6, and 8 in the diagram show well the "pulsus paradoxus." They were, with the exception of No 6, taken with the patient breathing quietly. During the time that No. 6 was taken the patient was asked to breath more deeply. The five tracings all show a condition of low arterial tension, Nos. 4, 5, and 6 being distinctly hyperdicrotic It is noticeable that where the paradoxical condition is most marked, as in No 6, there the pulse is most hyperdicrotic.

On March 15th 63 ounces of clear fluid were withdrawn from the right pleural cavity This was followed by considerable improvement in breathing and the patient passed a comfortable night. Pulse tracing No. 7 was taken on the evening of March 15th following the thoracentesis and shows a definite improvement. There is certainly a distinct respiratory curve but otherwise the tracing might pass for that of a normal pulse of low tension.

The above alteration in the pulse was undoubtedly brought about by the removal of the fluid from the chest and although the fluid did not re accumulate, so far as can be judged by physical signs, the paradoxical condition of the pulse returned as markedly as ever.

Tracing No 8 was taken on March 23rd, three days before the man's death, he was breathing quietly, though rapidly. The above tracings are all from the right radial artery; others were taken from the left radial artery presenting the same condition. It was impossible to obtain any tracings from the anterior tibial artery on account of the œdema about the ankles and feet. Unfortunately no necropsy was permitted.

I would like here to express my indebtedness to Dr. Nathan Raw, as it is through his kindness that I am able to publish these cases.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HEMIATROPHY OF THE TONGUE.

By L. A. Parry, M.D., B.S. Lond., F.R.C.S. Eng.,
LATE HONORARY ANÆSTHETIST, NORTH-WEST LONDON HOSPITAL.

THE following case is of interest not so much because of the condition of the tongue as on account of the unusual cause to which it was due.

The patient, a man, aged about 50 years, complained that one side of his tongue was growing smaller. He had no other trouble whatever, but he could not quite understand why this should be, and so he had sought medical advice. The condition present was simply atrophy of one side of the tongue. The only point in his personal history bearing on the case was that some years previously he had had a serious injury to his head, resulting in fracture of the base of the skull. Now, the causes of an unilateral atrophy of the tongue are disease of the hypoglossal nucleus or disease of the same nerve. Supranuclear disease is not accompanied by wasting, or, at any rate, only to the slightest extent. Facial hemiatrophy is sometimes accompanied by hemiatrophy of the tongue, but here this need not be discussed, for there was no hemiatrophy of the face. Nuclear disease is almost always bilateral and is generally accompanied by disease of adjacent nuclei, giving rise to labial paralysis. But every now and then in chronic degenerations, such as locomotor ataxia or progressive paralysis, of the insane, this affection is unilateral. Here, too, other nuclei are generally affected and other symptoms characteristic of the disease (tabes or progressive paralysis) are present. If the lesion is below the nucleus it may be (1) within the medulla, and then there is paralysis of the leg and arm of the other side; or (2) outside the medulla, then the nerve may be damaged within the skull by meningitis or new growths, or outside the skull by wounds, cellulitis, tumours, neuritis, or caries of the highest cervical vertebræ. There are no symptoms in this case of tumours, meningitis, caries, and so on, and I think this hemiatrophy is due to injury of the nerve in its passage through the anterior condyloid foramen at the time of the fracture of the base of the skull.

Hove, Sussex.

OCULAR PHENOMENA ASSOCIATED WITH CHEYNE-STOKES RESPIRATION.

By G. Young Eales, M.R.C.S. Eng., L.R.C.P. and L.M. Edin.,
LATE ASSISTANT DEMONSTRATOR OF ANATOMY, ST. GEORGE'S HOSPITAL, S.W.

THE following case is, I think, worthy of record inasmuch as the ocular phenomena observed, so far as I have been able to ascertain, have not hitherto been placed on record.

A man, aged 61 years, short, dark, and thick-set, came under my observation two and a half years ago, when I found him to be suffering from a mitral systolic murmur, considerable hypertrophy of the left ventricle, and some amount of albuminuria. Dilatation of the ventricle gradually ensued and this was followed by pulmonary and hepatic congestion, increase of the albuminuria, and, finally, general anasarca, so that it may be said that the patient was more or less waterlogged for the last two years of his life. Eight weeks before his death uræmic convulsions set in and continued off and on down to ten days before the end, when he became suddenly hemiplegic, after which the convulsions ceased. The patient was now paralysed on the left side and had in addition loss of control over the sphincters. Three days before his death coma accompanied by marked Cheyne-Stokes respiration supervened, which continued till his decease. I noticed that each cycle of this type of breathing averaged about a minute in duration, the intervals varying from 12 to 15 seconds and the respirations being from 28 to 33 in number. On examining the eyes I noticed that during the interval both pupils remained stationary and somewhat contracted. After the onset of the first four or five respirations each pupil began to dilate, and as the respirations increased in volume and rapidity they each became more and more dilated until finally they became widely dilated and remained stationary during the height of the cycle. As the respirations subsided during the decline of the cycle each pupil gradually contracted more and more until eventually, just before the respirations ceased, they became contracted somewhat and remained stationary till the onset of the next cycle.

I do not know that these ocular phenomena can be said to be a sign of diagnostic value of the disease under consideration; nevertheless, I deem it worthy to be placed on record, partly because it is an interesting piece of clinical evidence and may afford others the opportunity of being on the look-out for similar rhythmical pupil changes in cases of Cheyne-Stokes respiration, and partly because the whole phenomena of Cheyne-Stokes breathing is involved in obscurity. Many theories have been advanced to account for it, but none of them are quite satisfactory. Therefore, any side-light brought to bear upon the subject may possibly be of interest to those scientists who are interested in this matter. Sir W. Gowers, in his work on "Diseases of the Nervous System," says that the pupils may contract during the interval in Cheyne-Stokes respiration, but he is silent concerning any rhythmical action of the iris coincident with the rhythmical respiratory act such as I have stated above. Gowers, too, in speaking of Cheyne-Stokes breathing says that the respirations in each cycle never exceed 30 in number. In the case quoted above I frequently counted as many as 33 respirations.

Torquay.

LARGE DOSES OF CARBOLIC ACID IN EQUINE TETANUS.

By FRANCIS EVELYN PLACE, B.Sc., M.R.C.V.S.

DR. J. MITFORD ATKINSON'S case of bubonic plague[1] is of much interest, and as during the last two years I have been treating tetanus in horses by means of hypodermic injections of carbolic acid I send a few notes which may form an appendix to that case. The mode of procedure is to inject in the neighbourhood of the neck and shoulders one drachm of carbolic acid (British Pharmacopœia) every two hours for the first 32 hours of treatment and less frequently as occasion may arise afterwards. The result is that within an hour there is a large swelling at the seat of injection which gradually subsides during convalescence, and there is no trace of it left after 14 days in the case of those injections made during the virulence of the disease. Sometimes, however, in the case of the injections made during the subsidence of the disease there is a loss of hair. This occasionally persists for weeks, but in no case have I found it to be permanent. The largest amount used in a single case has been 36 fluid drachms in 84 hours, the patient being an Arab horse, 14 years old, which recovered and resumed work on the twenty-second day after the attack. I have never administered less than 16 drachms in a successful case and as in two cases I have seen horses die after the administration by the mouth of half an ounce of diluted carbolic acid given for pneumonia I can only conclude that in tetanus there is a specific tolerance of the acid and, judging from Dr. Atkinson's case, that the same seems to be the case in plague. Details of some of the cases I have treated may be found in the Transactions of the Bombay Medical Society for 1898, having been reported by the courtesy of Colonel W. G. Henderson, R.A.M.C., who has successfully adopted the treatment in human practice in relatively large doses.

SHEFFIELD ROYAL INFIRMARY.

A CASE OF TRAUMATIC TETANUS WITH RECOVERY.

(Under the care of Dr. W. DYSON.)

THE following case is a very good instance of a somewh severe attack of tetanus ending in recovery. The lo incubation period of 12 days was in itself of fairly good prognosis, for the chance of recovery increases with the length of time that elapses before symptoms appear. No antitoxin was injected, so we must attribute the satisfactory result to the excision of the wound and the administration of the bromide and chloral. The symptoms were so characteristic that we need have little hesitation in admitting the accuracy of the diagnosis, even though no tetanus bacilli were found. For the notes of the case we are indebted to Dr. Noel D. Bardswell, house physician.

A girl, aged 15 years, was admitted into the Sheffield Royal Infirmary on July 26th. There was a history of a cut on the right hand 17 days before admission and of its contamination with garden mould. The tetanic symptoms commenced somewhat insidiously 12 days after the accident with severe pain in the back, stiffness of the muscles of the neck and throat (causing dysphagia), spasmodic contraction of the jaws on attempting to eat or speak, and stiffness of the fingers and hand of the injured limb. During the next few days these symptoms increased in severity and she was then sent to the infirmary.

On admission all the muscles of the neck were in a condition of tonic spasm, the head being slightly retracted. The face was anxious-looking, the angles of the mouth were drawn downwards and outwards, and the pupils were widely dilated. Spasmodic closure of the jaws occurred incessantly, frequently biting the tongue, which was furred and much excoriated at its edges by the teeth. There was a slight degree of opisthotonos; the abdomen was unaffected. The legs were extended and stiff to move and all the muscles of the right arm, forearm, and hand were in a condition of tonic spasm, the fingers being firmly clenched and the arm flexed. On the right thenar eminence was a nearly healed healthy-looking cicatrix about an inch long. The paroxysms of spasm, which the least irritant would excite, occurred several times a minute, except for brief intervals, during which the patient dosed. During the paroxysm the distortion of the face became more pronounced, presenting a typical risus sardonicus; the jaws were tightly closed; the back was arched; the legs became rigid and slightly over-extended with the heels drawn up; and the contracture of the right arm and hand became more intense. The paroxysms were accompanied by great pain in the affected muscles and by profuse sweating. Respiration was unaffected, but the pulse was quickened during the paroxysms. The temperature on admission was 99° F.

The patient was kept in a darkened room; the cicatrix was freely excised, the removed tissue being kept for examination, and 20 grains of bromide of potassium and 10 grains of chloral were given every four hours. Under the influence of chloroform the spasm completely disappeared and the paroxysms were less severe for some hours following the administration. During the first week after admission she remained in much the same condition. There was slight irregular pyrexia, varying from 99° to 100°; the opisthotonos became more marked and tonic in character, and the muscles of the abdominal wall and left arm were contracted during the paroxysms, in addition to the muscles already mentioned. The constant biting of the tongue was the most distressing symptom and she kept a large piece of lint between her teeth day and night, which, she said, saved her tongue during the spasms. Sleep was greatly interfered with, difficulty was experienced in passing urine, which was reduced in quantit and febrile in character, and there was very obstinate constipation which was overcome by repeated doses of compound mixture of senna. Swallowing became easier after admission and she took fluid nourishment well between the paroxysms. On the third day after admission there appeared a universally distributed scarlatiniform rash, which gradually faded in the course of a few days, by which time the patient was becoming very weak, and 10 grains of bromide of ammonium, 10 minims of compound spirit of ammonia, and 15 minims of spirit of chloroform were given every four hours in place of the first mixture. Ten days after admission the condition began slowly to improve. Sleep became less disturbed and the paroxysms gradually became less frequent and severe, the muscles affected last being the first to recover. Convalescence was slow but steady, and in three weeks it was complete except for some stiffness of the affected area following the prolonged contracture.

---

[1] THE LANCET, Dec. 9th, 1899, p. 1622.

Bacteriological examination.—A bacteriological examination of the tissue excised was made by Dr. J. Robertson. The examination was commenced within an hour of the operation. The tissue was excised with aseptic precautions and received into sterile test tubes. Two pieces of tissue were received for examination—(*a*) a piece of fascia and (*b*) a piece of skin. In both instances the tissue was scraped in sterile water and teased; the water was then kept at 80° C. for 15 minutes, as recommended by Kitasato and a portion was added to glucose-agar and plate cultivations were made. These were incubated at 20° C. in an atmosphere of hydrogen. Several other media were inoculated and incubated at from 30° C. to 37° C. in Buchner tubes. The organisms were carefully examined and in many instances were subcultured. No bacillus tetanus was found, most of the organisms being facultative anaerobes. One diplococcus was of interest on account of the very extreme variations in size of the different cocci, some being from four to six times the diameter of others. Unfortunately, there was no opportunity of making any animal experiment.

LEEDS GENERAL INFIRMARY.

A CASE OF RUPTURE OF THE FEMORAL ARTERY.

(Under the care of Mr. W. H. BROWN.)

WHEN the trunk of the common femoral artery gives way either as a result of injury or from disease, gangrene of the leg is almost certain to follow unless the torn ends of the vessel be ligatured; the gangrene occurs partly because of the interference with the entrance of blood into the limb and partly because of the pressure of the effused blood on the femoral vein interfering with the return of the blood from the limb. In operating the external iliac artery is difficult to control and there is no better method of preventing hæmorrhage than the making of a "boutonnière" as described by Mr. Brown, so that digital pressure may be exerted directly on to the vessel.

A man, aged 33 years, was kicked by a horse in the left groin on Nov. 7th, 1899, two hours before he was taken to the Leeds General Infirmary. On admission there was a large swelling of the size of a cocoanut completely filling Scarpa's triangle and extending upwards over Poupart's ligament for about an inch. The skin over the tumour was tense and of a dark purple colour and appeared to be on the point of giving way. There was no pulsation to be felt. The limb was cold. The posterior tibial artery could not be detected. The patient was suffering great agony. As it seemed likely that unless active measures were speedily adopted the tumour would give way the patient was put under ether within half an hour of his admission. As it was not possible to apply a tourniquet owing to the position of the swelling an incision was made parallel to Poupart's ligament and about two inches above and the tissues were divided down to the peritoneum.

On introducing the finger the external iliac artery could be felt as a solid cylinder. Having obtained control of possible bleeding in this way an incision five inches long was next made through the skin over the swelling, revealing a large quantity of extravasated blood. This was rapidly removed and the cavity was thoroughly washed out with hot boric lotion. The pressure on the iliac artery was then relaxed and at the bottom of the wound a circular clot appeared, rendering the position of the torn artery clearly visible. There was also hæmorrhage from the distal end; this was also a serviceable guide, as the vessel had been completely severed and the ends were separated by an interval of about one and a half inches. The opened ends were ligatured by silk and the wounds were closed and dressed in the ordinary way.

The subsequent history was uneventful save that a week after the operation there was an elevation of the temperature with pain in the left side and rusty sputum. There was dulness over the lower third of the left chest; this gradually cleared up. The man was now again at work. The pulsation re-appeared in the posterior tibial artery a month after the operation.

Remarks by Mr. BROWN.—The foregoing case is, I think, worth noting for these reasons: (1) the fact that it is possible to have complete rupture of the femoral artery from such an injury and the vein to escape; (2) the method adopted to control the hæmorrhage; and (3) the importance of the earliest possible interference in like cases. Had the swelling given way before the operation the patient would have been exposed to the almost certain infection of the wound, which would have greatly added to the risk of his life even if he had escaped death from hæmorrhage.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on the Forms and Significance of Proteids in the Urine.

A MEETING of this society was held on Feb. 20th, Mr. PEARCE GOULD, Acting President, being in the chair.

Professor W. D. HALLIBURTON opened a discussion on the Forms and Significance of the Proteids in the Urine. He commenced by expressing regret that one with more clinical experience had not been selected for the position. He saw, however, the advantage of debates of this kind in which pathologists of the laboratory could compare notes with those of the bedside; coöperation of this kind was most useful in combating the disadvantage of over-specialisation. He further regretted that he had nothing startling or even new to bring before the society, but he hoped that his remarks might lead to something valuable being brought out by others. Their knowledge concerning the proteids was still most imperfect, but every year saw some progress made. They were substances of great molecular weight, and the large size of the molecules doubtless explained why in normal circumstances they were not able to pierce the barriers of renal epithelium except in the minutest traces. The proteid matter, however, of normal urine was chiefly contained in the nubecula. Still, Mörner had shown that there was a trace of serum albumin even in normal urine. Serum albumin was also most abundant in the so-called physiological albuminuria, the causes of which were briefly alluded to. But in Bright's disease serum albumin was usually mixed with serum globulin, as Senator originally showed. The proportion in which these two proteids occurred still required to be more thoroughly worked out. But as a rule (to which there were occasional exceptions) the globulin was less abundant and the presence of much globulin was generally a serious condition. Some evidence was adduced to show that the molecules of globulin were larger than those of albumin, so the abundance of the latter could be accounted for on physical grounds. It was only after the renal epithelial cells were greatly damaged that globulin could make its way through them. Some exceptional conditions, such as Byrom Bramwell and Noël Paton's case of crystalline globulin in the urine, and cases of fibrinuria were mentioned. The fibrinogen molecule was probably still larger than that of serum globulin, hence its comparative rarity in the urine. A similar explanation would explain the fact why caseinogen of milk had never been found in cases where lactose was discoverable. Passing rapidly in review other and rarer urinary proteids Professor Halliburton dwelt next more especially on those with small molecules and distinguished between peptonuria and albumosuria. The former term should be restricted to those morbid conditions, usually of suppurative nature, in which bacterial digestion led to the formation of proteolytic products which were mainly cast out from the body by the kidneys. The substance most however, true peptone in Kühne's sense, but deutero proteose. The term "albumosuria" was usually restricted to those rare cases in which, owing to osteomalacia and certain other bone diseases, the form of albumose that passed into the urine was hetero albumose. Only a few such cases had been fully recorded hitherto, and though there were small differences between the various cases they on the whole agreed fairly well with the description originally given by Bence Jones.

Dr. T. R. **BRADSHAW** (Liverpool) read a paper on the Forms and Significance of the Proteids found in the Urine in Myelopathic Albumosuria, a condition of which 11 authentic instances had hitherto been recorded. One example of the disease had been under his observation. The patient was a man aged 70 years. The illness had apparently commenced about a year before he died. There was extensive disease of the bones; but the most notable feature of the case was the voiding of milky urine. This was due to the presence of a proteid substance which was frequently precipitated spontaneously so that the urine presented an opaque white colour when it was passed. The most characteristic reactions given by this urine were the formation of a precipitate below 60° C. and precipitation by nitric acid and hydrochloric acid in the cold, all the precipitates being more or less soluble on boiling. The heat precipitate was entirely dissolved, without apparently undergoing any change in its nature, by a solution of caustic soda (1 per 1000). Careful analyses seemed to show that the proteid present was all of one kind, at least that if any other was present it was only in traces. As regards its nature, its reaction with nitric acid showed that it was an albumose, but it was doubtful whether it could be identified with any of the albumoses known to physiological chemistry. The balance of evidence pointed to its being an albumose of a peculiar kind which had not been found in any other conditions. Clinical experience showed that its appearance in the urine was the earliest available indication of an affection of the bones of the trunk, which, as far as their experience went, always proved fatal. Dr. Bradshaw demonstrated the characters and reactions of the urine and exhibited micro- and macro-scopic specimens taken from the case.

Dr. **ROBERT HUTCHISON** described a Peculiar Proteid found in the Urine of a man who subsequently died from multiple myeloid sarcoma. The proteid differed from the body first described by Bence Jones in these cases in being an albumin and not an albumose. But it also differed from all other albumins in having a very low coagulation point (58° C.), in being very readily denaturalised, and only slowly precipitated by acetic acid and ferro-cyanide of potash. Otherwise it gave all the reactions common to albumins. It contained no phosphorus and was not precipitated by ammonia, and was therefore not a nucleo-proteid. No chemical examination of the tumours could be made, but the case was undoubtedly one of multiple myeloid sarcoma, as verified by the necropsy, the neoplasm consisting of a large round-celled sarcoma. The urine presented no visible deposit; it was clear, of low specific gravity, and slightly alkaline.

Dr. F. W. **PAVY** remarked that he did not think albumin in any form could be found in healthy urine and they could not properly speak of physiological albuminuria though functional albuminuria might occur. On the other hand, as regards sugar that was a very different matter. This was a much more diffusible substance and the molecule very much smaller. He believed that the action of the kidneys as regards proteids might be likened to filtrative or osmotic processes, the activity of these processes depended on the amount of pressure and the size of the molecules. If the normal pressure in the renal vessels were slightly increased then albumin passed into the urine. He thought that perfectly healthy urine was not devoid of a certain kind of proteid—viz., nucleo-albumin or mucin—but only in small quantity, not sufficient to be detected by ordinary tests. These were thrown out from the surface of the urinary tract. This nucleo-albumin was the great rock on which observers split. But as regards the other proteids they appeared in urine as the result of diffusion. In peptonuria and albumosuria the proteids consisted of larger molecules. These were synthesised, but peptone and albumose appeared in urine as a result of the laws of osmosis. In general terms albumin was not a grave sign, as might be judged from the fact that in the most lethal of the renal affections (granular kidney) albumin might be altogether absent. He thought the circumstance that serum albumin was larger in quantity than serum globulin was quite accounted for by the fact that the former was more diffusible. Dr. Pavy then referred to the observations he had made on a man named Weston who walked at the Agricultural Hall 100 miles in 24 hours. At the end of 24 hours his urine was loaded with albumin and with casts. The dependence of proteids in the urine on the vascular condition of the kidneys was well exemplified by cyclic albuminuria. In this condition in the morning there was no albumin; after breakfast and when going about the albumin appeared. It was absent usually at night. This condition of matters went on all the year round. Such subjects were of a very "mobile" nature. Their vessels were easily influenced. The renal vessels were subjected to additional pressure when a person assumed the vertical posture. Dr. Coupland had noticed that a patient of his had albuminuria whenever she got up—i.e., during the morning—but it disappeared when the patient went to bed in the afternoon. He (Dr. Pavy) submitted that this was due to the altered state of pressure in the vessels of the kidney. No one had shown that the proportion between the serum albumin or serum globulin was a matter of any clinical or pathological significance. Moreover, the total amount of albumin was of no very great importance. The important data consisted of the presence of casts and the amount of urine passed; these were the measure of the gravity of a case.

The discussion was adjourned to the first meeting in April.

HARVEIAN SOCIETY OF LONDON.

The Feeding of Infants with Modified Milk.

A MEETING of this society was held on Feb. 15th, Dr. W. H. **LAMB** being in the chair.

Dr. G. F. **BLACKER** communicated some remarks upon the Feeding of Premature or Delicate Infants with Modified Milk. The majority of delicate infants throve best if fed upon the breast, and where the child could not be put to the breast directly the milk should be drawn off and given in a bottle. In premature delivery the breast milk retained its colostral properties longer than normal, often disagreeing with premature children, and for the majority of such children cows' milk was a suitable substitute when diluted. Any of the cream mixtures in common use would do quite well. In cases where cows' milk caused marked gastric disturbance modified milk or the method of ordering a mixture of cows' milk of varying composition according to the individual needs of the particular child would seem to be a distinct advance in the scientific feeding of young infants. The chief difference in the composition of cows' milk or human milk was in the relative percentage of the proteids and the fats. The modification of the strength of cows' milk to any degree was an easy matter. The mixtures of cows' milk and water given to infants were markedly deficient in fat. Modified milk contained a cream of stable composition and the amount of fat could be accurately regulated. Modified milk had the advantage in that it was made up with milk sugar and not with cane sugar. Milk laboratories for the preparation of modified milk were quite recent institutions in this country. The milk, carefully selected, was filtered and cooled to 40° F. The whole milk was then treated in a centrifugal separator, by which not only all the cream but also any dirt or foreign particles were separated out. The percentages of proteids and sugar varied little in selected milk, but the percentage of fat varied from day to day When the percentage of fat had been estimated in each day's milk-supply the milk was ready to be combined in the modifying-room according to the prescription sent in. The materials used were cream with 16 per cent. of fat, separated milk, a 20 per cent. solution of milk sugar, and lime-water. The food was put up in tubes each containing the amount required for one feed with a plug of sterile cotton-wool The tubes were then heated to 167° F. and then cooled to 38° F. In writing a prescription for modified milk it was best to order a small percentage of proteid to begin with and gradually increase the amount. The advantages of modified milk were that the exact composition was known, that the milk only required warming before being given, that no cleansing of the bottles was required, and that there was not that daily variation noted which was observed in ordinary cows' milk. The disadvantages of modified milk were that it entailed an increase of trouble to the medical attendant. Pasteurised or sterilised milk administered for long periods of time was apt to lead to the production of low forms of malnutrition, while the milk was only applicable to a certain class owing to the cost. Dr. Blacker concluded by stating that he considered that modified milk was under certain conditions undoubtedly of great service in the feeding of delicate infants, and he now ordered it in cases where it was not possible to get a suitable milk-and-cream mixture made at home, and where otherwise condensed milk or asses' milk would have to be used, or a wet nurse obtained.

Dr. R. BOXALL remarked on the difficulty and expense obtaining modified milk except in large centres. If their milk supply were regulated as, for instance, he had observed in the Eifel district of Germany, where a well-ordered public milk establishment was to be found in every village and hamlet, even among the poorest, modified milk could be readily obtained anywhere.

Dr. A. P. LUFF stated that in his opinion the method of preparing the milk described by Dr. Blacker was not without its possible drawbacks, in that the important anti-scorbutic elements of the milk might possibly be altered by the treatment employed. Although it was extremely desirable that the milk should be free from tubercle bacilli yet there were many beneficent bacteria which it was necessary for the health of the child should remain intact in the milk.

Dr. E. CAUTLEY and Dr. G. A. SUTHERLAND also discussed the paper.

Mr. FRANCIS JAFFREY read a paper on a case of Suppression of Urine of 60 hours' duration treated by operation which we hope to publish in an early issue.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases, &c.

THE fifth meeting of this society for the present session was held in the Royal Infirmary, Newcastle-on-Tyne, on Feb. 8th, Mr. A. E MORISON, the Vice-President, being in the chair.

Mr. RUTHERFORD MORISON brought forward three patients operated upon for Abscess in connexion with the Appendix, illustrating points which he wished to raise. The first of the patients, a boy, was seen on the ninth day of his illness, without temperature but with a tender swelling in the right iliac fossa On operation an abscess was found containing an ounce of pus on the inner side of the cæcum. The appendix was perforated and a loose stercorolith was lying in the abscess cavity. The presence of pus, Mr. Morison said, was an undoubted indication for operation, but in certain cases it was difficult to diagnose. If after the fourth day there was a tender mass the patient was the subject of appendicular abscess and therefore operation should not be delayed. The second patient, a boy, had had four previous attacks and on the fifth occasion he was seen to be seriously ill with doubtful diffuse septic peritonitis. In this case the abscess was simply incised and six months later the development of a similar illness occurred with a localised abscess which this time burst into the cæcum. On the seventh attack operation was undertaken before rupture with removal of the appendix. Mr. Morison strongly advocated removal of the appendix in suppurative cases. He had operated in six cases lately in which after simple incision attacks had recurred In the case of the third patient, a girl, a hole was found upon operation communicating with the cæcum. Bursting of the abscess, then, was a not uncommon occurrence and might terminate in recovery without operation, but operation, by determining the direction of the evacuation of the pus, undoubtedly gave the best chance. Mr. Morison laid stress upon the following points (1) the diagnosis of pus was largely determined by the presence of a tender mass; (2) even in the presence of an abscess the appendix should be removed, otherwise attacks might occur; and (3) such abscesses by bursting into the cæcum might terminate in cure—which was a result, however, neither to be waited for nor relied upon. Mr. Morison then showed a series of diagrams illustrating the various positions in which appendicular abscess might occur, and the anatomical positions taken by the vermiform appendix —Dr. J CLAY, Dr. BEATTIE, and Dr JAMES DRUMMOND took part in the subsequent discussion

Dr. ALBERT M MARTIN showed a child, aged 11 weeks, who was born after a somewhat severe and tedious labour and at birth did not recover for 15 minutes Since birth the present condition had developed. The arms were rotated in at the shoulders, the forearms were markedly supinated, rigidity being very evident, and the legs showed slight rigidity with exaltation of reflexes. There was no muscular wasting and no facial palsy. Dr. Martin took the view that the lesion was a hæmorrhage into the motor cortex and that this had probably resulted from asphyxia at birth. The treatment of the case was discussed and also its prognosis. Dr. Martin mentioned that these cases improved up to a certain point as the patient grew older, the legs, as in this case, showing earlier and more complete improvement than the arms.

Dr. MARTIN also brought forward a child, aged six months, who had had a Circumscribed Fluctuating Mass in the Right Side of the Neck since birth. It was no doubt a dermoid in connexion with the second bronchial cleft.

Dr. G. H. HUME showed a woman, 51 years of age, who three years ago developed stomach symptoms, with a Moveable Nodular Growth in the Situation of the Pylorus. Eighteen months after pylorectomy with removal of the glands a small nodule of doubtful character was noticed in the skin cicatrix. This did not quickly increase in size, and one year later at a second operation a hard malignant nodule in the margin of the liver to the left of the gall-bladder was removed after the application of an elastic ligature, the stump being treated extra-peritoneally. The patient made a good recovery, the wound having almost healed.

Dr. HUME also showed two men who had had symptoms of Dilatation of the Stomach for many years and after pyloroplasty had rapidly improved in their general condition, increase in weight being a prominent feature. Dr. Hume advocated the exploration of doubtful stomach cases, and emphasised the expediency in these cases of early operation.

Dr. T. OLIVER showed a man, aged 49 years, who had had a severe attack of Influenza five years ago which prevented him from working for six months. He had never been well since, and two years ago his present symptoms developed and had subsequently increased. He now displayed marked weakness and atrophy of the deltoids and of the muscles of the upper arms and chest and weakness of the legs with extensive fibrillation, together with increased reflexes. Along with this condition there was paralysis and atrophy of the tongue and of the orbicularis oris.

Dr. OLIVER also showed a drawing and specimen of a Pedunculated Tumour of the Labium which had been successfully removed.

Mr. WATSON showed a photograph of an unusual example of Hare Lip with Cleft extending into the Nose from the non-development of the fronto-nasal process.

PATHOLOGICAL AND MICROSCOPICAL SECTION.

Spinal Descending Degeneration.—Ascending Tracts in the Spinal Cord —Parasite of Cancer.—Exhibition of Specimens.

A MEETING of the above section was held on Feb. 15th, Dr. J. HILL ABRAM being in the chair.

Professor SHERRINGTON and Dr. LASLETT exhibited specimens from the Spinal Descending Degeneration produced in a dog by a semi-transverse section through the spinal cord performed at the region of the fourth lumbar nerve. The degeneration was practically confined to the half of the spinal cord on which the lesion had been made. The specimens had been prepared by the "Marchi" method. There were numbers of descending degenerate fibres in the ventral as well as in the lateral column of the cord.

Dr. WARRINGTON read a note describing an investigation carried out conjointly with Dr. Laslett on Ascending Tracts in the Spinal Cord of the Human Being. Two separate tracts were demonstrated and their course traced to the cerebellum.

Mr. KEITH MONSARRAT read a paper on the Parasite of Cancer. He had isolated an organism from carcinoma and had grown it upon various media, obtaining cultures from which inoculations had been made into the peritoneal cavity of guinea-pigs with the result that they developed new growths on the peritoneum and secondary growths in the internal organs. In these growths the parasitic organism was found in abundance and a further series of cultures were made. He stated that although the parasitic origin of cancer was far from proved, it was nevertheless a good working hypothesis. The explanation of the uniformity of primary and secondary growths he considered was to be found in the intra-cellular migration of the parasite, so that the cancer cells carried within them to the new nidus the stimulus to their own multiplication and the cell type in this way remained the same. A description was then given of the parasites as observed in carcinomata, the considerable diversity of form being shown by micro-photographs, and a selective method of staining was described which had demonstrated several new points in their morphology. A comparison of the isolated organism and the "cancer-bodies" showed that morphologically they appeared to be identical, accounting for varieties of form in each. The investigation had been assisted by a grant from the British Medical Association. The paper was profusely illustrated by means of microscopic specimens, photo-micrographic transparencies, and coloured lantern slides.—Mr. F. T. PAUL, whilst admitting the presence of the bodies described, maintained that proof was still entirely wanting that they were the cause of cancer.—Professor BOYCE, Professor SHERRINGTON, Sir WILLIAM M. BANKS, and others also took part in the discussion.

The following specimens were shown:—

Mr. F. T. PAUL: Malignant Tumours of the Parotid Gland.

Mr. RUSHTON PARKER: (1) Stomach after Gastrostomy; (2) Pelvic Contents from a case of Obstruction of the Rectum; and (3) Odontoid Process of the Second Vertebra Detached and Bare from periostitis and caries.

Mr. KEITH MONSARRAT: Urethro-vesical Calculus.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—The January meeting of this society, Dr. C. E. Beevor being in the chair, was devoted to a discussion on Syphilis.—Mr. Albert Ehrmann showed a typical case of Primary Syphilis in a young man. The sore was on the prepuce. A macular eruption was just visible on the skin of the abdomen eight to nine weeks from the date of infection. Commenting upon the case Mr. Ehrmann said that in the treatment of syphilis by inunction as carried out at Aix-la-Chapelle the skin was usually considered to be in a fit condition for the absorption of mercury on the third or fourth day after the arrival of the patient. The dose used at first was from two grammes to three grammes daily, and this might be increased to four grammes or five grammes if the process was well borne. The latter dose was only increased in exceptional circumstances. The parts of the body where the mercurial ointment must be rubbed in from day to day were five in number. The two legs were treated on the first day, the two thighs on the second day, the chest and the abdomen on the third day, the back on the fourth day, and both arms on the fifth day. The nipples, the navel, and very hairy parts of the body were to be carefully avoided, for in these acne and eczema were easily induced by the rubbings. A great deal was said to depend upon the mode of rubbing. The rubbers were trained in making the inunctions with both hands with the proper force and for the proper length of time. The inunctions were made for the most part with the unguentum hydrargyri cinereum. The morning was considered the most favourable time for anointing, but not immediately after the bath, since the skin was then moist and the pores were filled with water and were not adapted for absorption. It was not advisable to perform inunction at bedtime, for perspiration was increased in bed and many patients became restless and could not sleep after the inunctions. Every day the patient took a half hour's bath at a temperature of 96·5° F., in which he removed the remaining portions of mercurial ointment, and every morning he drank from two to five glasses of thermal water. In many cases, about from the fifteenth to the twentieth inunction, a period arrived at which there was a diminution in the powers of absorption of the skin. After the twentieth day of treatment a steam bath of from 10 to 15 minutes' duration was taken on alternate days or on every third day. After the steam bath an ordinary bath was taken for 10 minutes, followed by a cold douche to prevent chilling. With regard to the manner in which the mercury entered the system Wings thought that there was a direct transit of mercurial vapour, while Fürbringer said that there was a chemical change in the metal deposited in the skin by combination with the secretions of the skin. Wings found that the quantity of mercury volatilised in the skin and penetrating through that tissue in 24 hours was equivalent to the usual dose of perchloride of mercury used in intramuscular injections. The real effect of the thermal sulphurous waters in aiding specific remedies in syphilis was due partly to the beneficial effect of the spa treatment on general nutrition and in part to their direct action on the skin. Neisser said that during the inunction treatment the baths washed away some of the mercury which would otherwise be absorbed and the sulphurous baths converted some of the mercury into the inactive sulphide. He suggested that sulphurous waters might help to ward off mercurial enteritis and that even common salt waters might be of use by their action of favouring metabolic processes generally, and also those undergone by the mercury in its "passage through the system." In the treatment of the later stages of syphilis, while the value of iodide of potassium was recognised the leading rôle was still given to mercury. This drug had apparently the real curative effect, while the former, by causing the rapid disappearance of symptoms, might induce a feeling of false security in many cases.—Dr. A. Whitfield, in discussing the treatment of syphilis in the earlier periods, referred to the question as to when mercurial treatment should be first instituted. He said that he should be inclined to give mercury directly he was certain of his diagnosis, and he gave as the points upon which he would rely the cartilaginous consistency of the sore, thickening and induration of the dorsal lymphatics of the penis, elastic and painless swelling of the glands in the groins, and, if all these were not pronounced, general adenitis. In those cases in which such a chain of symptoms was not well marked he would prefer to wait for the early rash before committing his patient to a long course of mercury. He believed that the question at issue between those who liked to wait for the development of rash before instituting treatment and those who began treatment at once was not of serious importance. In Germany and Austria the waiting plan was almost universal, and the results did not seem to be inferior to those in this country. As regards the preparation of mercury which he preferred, he might say that he was in the habit of always using grey powder in small doses (one grain) two or three times a day. It was a good plan also to prescribe a gargle of chlorate of potash for use as a mouth-wash in every case. This acted more or less as a prophylactic against stomatitis. In some cases he gave iodide of potassium quite early in the disease, usually merely to relieve symptoms, such as severe headache, osteocopic pains or joint pains, or if the throat condition was severe and appeared aggravated by mercury. In such cases it was as well to cut off the mercury and to use iodide and local gargles until the throat was well, when the mercury should be recommenced. In late syphilis of the skin he relied to a greater extent on local remedies, but he always gave mercury internally, whether with iodide or not, as he believed that relapses were less common with such treatment. He called attention to a form of treatment for cachectic and malignant cases which was seldom used in this country—viz., Zittmann's decoction. The method was extremely full of detail as to diet, temperature of room, &c., but the results were such as to justify the trouble taken. The medicinal treatment consisted mostly of a mixture of alum, senna, and sarsaparilla with minute quantities of calomel. Dr. Whitfield showed two cases illustrative of late syphilis and irritation. Case 1 was that of a woman with a history of syphilis five years before who was now suffering from two patches of grouped papules below the left patella, the more marked of the two being situated just where kneeling would irritate the skin. It was pointed out how like this form of eruption was to lupus, but the superior hardness and the more rapid formation of the syphilide cleared up the diagnosis. Case 2 was that of a man with a subcutaneous gumma which had formed just where a strap which he wore on his arm chafed him. His original attack dated apparently from more than three years before but he was not clear as to his history.—Dr. W. H. Day, who advised circumcision for Mr. Ehrmann's patient, Dr. G. F. Blacker, Mr. H. S. Elworthy, and Mr. Mower White also took part in the discussion.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—The first ordinary meeting of this society was held on Feb. 5th, at Chandos-street, Cavendish-square, Sir William Dalby, the President, being in the chair. After lamenting the death of Dr. Charles Delstanche of Brussels the

President gave an inaugural address, which was published in THE LANCET of Feb. 10th.—Dr. Urban Pritchard then read a paper on Antiseptic Purification of the Meatus and Adjacent Parts, both for Operation and as a Treatment of Chronic Middle-Ear Suppuration. It was pointed out that antiseptics could be applied to the meatus and intact membrane in the same way as in other parts of the body with similar results, and also that an initial thorough purification of the middle ear and meatus followed by careful packing with double cyanide gauze was an excellent method of treating certain cases of chronic middle-ear suppuration.—A discussion followed in which the President, Mr. A. E. Cumberbatch, Dr. A. Bronner, Dr. Milligan, Dr. Macnaughton Jones, and Mr. Arthur Cheatle took part.—Dr. Milligan read the notes of a case of Cerebellar Abscess which he had recently operated upon. The intracranial lesion followed an attack of acute middle-ear suppuration of only a few weeks' duration. During the first operation sudden paralysis of the respiratory centre intervened necessitating the evacuation of the abscess being performed while artificial respiration was kept up. A month later it was found necessary again to explore the cerebellum when another abscess was found and drained, but although the patient rallied from the operation death occurred. At the post-mortem examination no macroscopical connexion between the ear and cerebellar lesion could be found.—Mr. Ballance, in discussing the case, suggested that the abscess had no connexion with the middle-ear trouble and cited some cases of the late Dr. Bristow in which abscesses in various parts of the brain were attributed to influenza. He had operated on three cases of cerebellar abscess during artificial respiration. He found that the best organ for exploring the brain was the finger and drew attention to a thin oyster shaped abscess which was occasionally present immediately underneath the tentorium and of which he had seen three instances.—Dr. Urban Pritchard showed a patient from whom a large Cholesteatomatous Mass had been removed through the Meatus. The disease had completely hollowed out the antrum and mastoid process and by eroding the posterior meatal wall had laid these cavities open into the meatus.—Dr. Dundas Grant showed a case of Thrombo-phlebitis of the Lateral Sinus treated by operation without ligature of the internal jugular vein, with recovery. When the sinus was laid open it was found that the septic contents were bounded above and below by healthy-looking clot.—Dr. Herbert Tilley showed: 1. A large mass of Cholesteatoma removed from a boy, aged 14 years. The middle-ear, antrum, attic, mastoid process, and meatus were converted into one cavity by the disease. 2. A mass of Cholesteatoma which was removed through the meatus, the removal practically curing a distressing cough from which the patient had been suffering.—Mr. L A. Lawrence showed an elderly woman with a Papillomatous Growth growing from the Meatal Wall. The microscopical section was shown.—Mr. Arthur Cheatle showed (1) a woman, aged 28 years, in whom he had removed a large part of the Auricle and the whole of the Meatus for an Adeno-carcinomatous Growth, which started in the posterior cartilaginous meatal wall. The operation had been performed one year and three months previously and there had not been any recurrence since; as the meatus could not be kept open, and as chronic middle-ear suppuration existed, the complete post aural operation had also been performed, and a permanent opening behind the remains of the auricle established. The specimen and microscopical section were also shown. 2. A boy, aged 14 years, who had recovered from septic thrombosis of the lateral sinus without ligature of the internal jugular vein. The septic contents were limited above and below by healthy clot.—Dr. Ernest Waggett showed a case of Sequestration of the Cochlea in a case of cured Cerebellar Abscess. Since the description of the case at the last meeting of the British Medical Association a portion of the cochlea had come away. The specimen was also shown.—The discussion on the cases shown by Dr. Dundas Grant, Dr. Waggett, and Mr. Arthur Cheatle was adjourned until the next meeting on March 5th.

WEST PENWITH (CORNWALL) MEDICAL SOCIETY.—A meeting of this society was held at Penzance on Feb. 14th, Mr. W. S. Bennett, the Vice-President, being in the chair. Two new members were elected.—Dr. F. Chown read a paper on Some Points in the Prevention and Treatment of Diphtheria. Dr Chown advocated the determination of quarantine in each case by bacteriological tests, facilities for which should be supplied by sanitary authorities. For treatment thorough local antisepsis was demanded. Antitoxin he had not found of much value. In paralytic cases strychnine (subcutaneously if necessary, especially where cardiac dilatation supervened) and naso-pharyngeal or rectal feeding were most useful. In laryngeal cases the old ipecacuanha treatment with steam tent was generally good. Small doses of chloral were called for if much spasm of the glottis existed. A consensus of opinion declared in favour of the power of antitoxin in loosening the membrane. Epigastric retraction, which might, however, be exaggerated in rickety children, and cyanosis, which was a symptom of unmistakeable significance, were indications of the need of operative interference. Tracheotomy was preferred to intubation, as it was more easily performed, as the tube was more constantly retained, and as greater facility was given for the mechanical detachment of membrane. A useful point of technique for the inexperienced operator was the tearing of the parts with two pairs of spring dressing forceps after the skin and fat had been cut through.—Dr. H. M. Montgomerie showed a young Albino Girl and contributed notes on three cases of Cerebral Embolism: (1) a female, aged 59 years; (2) a female, aged 29 years; and (3) a male, aged 36 years. In the first case there was profound coma, gradually disappearing; in the second case there was semi coma passing off in a few days; and in the third case no mental disturbance was perceptible. In all three cases there was complete right hemiplegia for a time. In Case 1 there were complete anæsthesia and total aphasia. On the fifteenth day slight power recurred in the right foot; this power and sensation gradually increased. Eighteen days later "yes" and "no" could be indistinctly uttered. Motor aphasia with word-blindness and word-deafness, for a time complete, were very slowly recovered from. There was also for a time complete loss of bladder control. The patient was a subject of chronic bronchitis with mitral heart. In Case 2 the patient was hemiplegic. He had epileptic attacks at long intervals for some years and eight years before the hemiplegic attack had acute rheumatism, leaving aortic stenosis. Anæsthesia was partial and aphasia was considerable; there was marked word-deafness with word-blindness. Bladder control was unimpaired. In Case 3, though the hemiplegia was at first complete, slight movement in the right foot returned within 24 hours and slight movement in the right arm on the following day. On the fifth day the thumb and index finger could be for the first time a little moved. Sensation was very little dulled and there was for the first day or two a slightly perceptible slurring of speech. There was never the least sign of want of control over the bladder. In this case there was a history of pulmonary catarrh with slight hæmoptysis. Case 1 occurred eight months ago, Case 2 11 days ago, and Case 3 in November, 1895. All the patients were still alive.—After a short discussion on the papers the members of the society present dined together.

IPSWICH CLINICAL SOCIETY.—The annual meeting of this society was held on Feb. 8th at the East Suffolk and Ipswich Hospital Mr. Hoyland, being in the chair.—Mr. C. K. Moseley was elected President for the ensuing year and Mr. Walter Sinclair was re-elected honorary secretary. The following were elected members of the Council: Mr. R. W. Brogden, Dr. H. H. Brown, Mr. J. F. C. Hossack, Mr. S. S. Hoyland, Mr. J. R. Staddon, and Dr. F. Warner.—Mr. Walter Sinclair showed (1) a case of Interstitial Keratitis, and (2) a case of Lamellar Cataract, with remarks on the cause and the treatment of these conditions.—Mr. R. W. Brogden showed a man with Peculiar Nervous Symptoms. The patient walked with his feet wide apart and dragged each leg slightly. When asked to stand with his feet together and his eyes closed, he staggered backwards with a succession of short steps on his heels. On attempting to carry a glass of water to his mouth his hand trembled markedly, and at times, when standing, his legs trembled so violently that the whole ward was shaken. The knee-jerks seemed somewhat exaggerated, but varied. There were no clonus, no pupil symptoms, and no ophthalmoscopic abnormality. The patient referred his condition to an injury to the spine. Most of those present agreed with Mr. Brogden's opinion that the patient was probably a malingerer.—Mr. Wynne Davies showed a well-marked case of Ichthyosis in a child. No history could be be obtained. The skin disease was recovering rapidly under salicylate ointment, and thyroid extract given internally.—Mr. C. K. Moseley referred to the frequency with which a history of "maternal impression" was given in these cases.—Dr. H. H. Brown showed a Tumour weighing five pounds which was removed by Mr. Dean. It was a myoma taking its origin from the cervix and growing between the layers of the broad ligament. It caused almost no symptoms and the patient was doing well.—Dr. Brown also showed an Apparatus which he had devised for treating Dislocation of the Acromial End of the Clavicle. Such dislocations were easy to reduce, but it was notoriously difficult to keep the bones in position. His apparatus had given an excellent result in the case for which it was devised.

Glasgow Pathological and Clinical Society.—The fifth meeting of this society was held on Feb. 12th, Dr. Thomas Barr, the President, being in the chair.—Dr. T. K. Dalziel showed:—1. A series of seven cases of Gall-stones removed from the Bile Ducts. 2. Two patients, mother and daughter, on whom he had operated several times for Sarcoma with Recurrence. The mother had a sarcoma of the left lacrymal gland removed in 1892. At intervals of 12 months the following parts became affected and were successively removed: (*a*) the floor of the orbit, the eyeball, and the lower lid; (*b*) the cheek down to near the margin of the upper lip; (*c*) nodule at the angle of the jaw; and (*d*) a mass over and involving the mastoid process. Seven months later the superior maxilla was excised, followed in eight months by the pterygoid process, the soft palate, and the lateral wall of the pharynx. The daughter had the right lower jaw excised with a mass of lymphatic glands, and six months later an enlarged gland was removed from the region of the cicatrix. All of these tumours presented the characters of round-celled sarcoma. 3. A Calculus from a Male Bladder with Nucleus formed of a piece of Indiarubber Tube of an Infant's Feeding-Bottle.—Professor Muir exhibited the Kidneys from a case of Diabetes. The organs showed extensive infection by staphylococci—Dr. D. N. Knox showed a Piece of the Jejunum Obstructed by a Large Gall-stone.—Dr. Ebenezer Duncan showed (1) a Calcification of the Pericardium; (2) a specimen of Mitral Stenosis; and (3) a Carcinomatous Tumour at the Root of the Left Lung pressing on the Bronchus and on the Œsophagus.

Manchester Medical Society.—A meeting of this society was held on Feb. 7th, Dr. T. C. Railton, the President, being in the chair.—The President delivered his presidential address on Infant Mortality and dealt with the increasing mortality among young children in large towns from diarrhœa and dietetic diseases. The necessity for the centralisation of the milk-supplies in large establishments, where pasteurising and humanising milk could be carried out under scientific supervision before distribution to the retail milk dealers, was urged and the growing employment of proprietary foods was condemned. He advocated a much wider intervention on the part of the profession in public affairs, especially in institutions having an influence upon child life, and suggested the more frequent delivery of popular lectures for the education of the public as to the proper methods of bringing up children.—Dr. W. E. Fothergill communicated a paper on the Results of the Administration of Salol and of Petroleum in Infantile Diarrhœa. The cases were observed by Dr. John Penny and himself at the Chorlton Dispensary during the summer of 1899. In 35 cases salol was used. Two children died, six did not recover until other drugs were used, while the remaining 27 cases recovered rapidly and completely under the influence of salol alone. An emulsion containing 33 3 per cent. of petroleum was given in 32 cases. One child died, two recovered slowly after the exhibition of other drugs, and the remaining 29 cases ended quickly and favourably after treatment by petroleum alone.

Oxford Medical Society.—The fourth meeting of the session was held on Feb. 9th, in the Anatomical Theatre, when Dr. Ramsden read a paper on the Clinical Value of Blood Examinations, illustrated by diagrams and microscopic specimens. After urging the importance of this subject he proceeded to describe what seemed to him to be the best methods and gave a number of instances where such examinations had proved practically useful. The significance of the various leucocytes, normal and abnormal, and of the alterations in their quantitative relations were discussed, and it was maintained that, whether for diagnosis or prognosis, the blood often gave indications of considerable value. For blood-films Jenner's method of staining was strongly recommended as the simplest and most satisfactory yet devised and as quite sufficient for all clinical purposes. Dr. George Oliver's hæmoglobinometer was the most accurate, but Sir William Gowers's instrument was sufficiently so if precautions were taken to employ a correct standard, and if the true reading was taken as the mean of the dilution which was just insufficient and of that which was just too much. Estimations of fibrin were of little practical value, as the methods used were open to serious objection. Nucleated red blood corpuscles were specially apt to appear in the general circulation in Bright's disease. Their absence together with the absence of eosinophilous cells in cases of severe anæmia was a bad sign.

Æsculapian Society of London.—A meeting of this society was held on Feb. 16th, the Vice-President, Dr. B. G. Morison, being in the chair.—Mr. E. C. Hearne showed a young woman who in November, 1891, had Hyalitis, so that only the upper part of the fundus oculi was visible, and the patient's sight in the affected eye was reduced to perception of a hand at 50 centimetres. The defect had been increasing for a year and was thought to have been induced by a fall on the nose, after which an internal squint soon developed in the affected eye. In seven months the condition had not improved. In April, 1898, the vision of the affected eye was $\frac{6}{6}$ Jaeger 1.—Mr. E. C. Hearne also read notes of a case of Ptosis with Paresis of the External Rectus and a Dilated Sluggish Pupil in a fat man who had had syphilis three years previously. Under the administration of iodide of potassium (0·6 gramme three times a day) the ptosis and glycosuria, previously very marked, completely disappeared, but still left some external rectus paresis, though less.—Dr. C. G. Mack read notes of a case of a man, aged 41 years, who suffered from increasing intestinal colic with constipation. A median laparotomy was performed by Mr. A. H. Tabby who found the sigmoid flexure encircled by a malignant growth. Accordingly a lateral colotomy was carried out. The result was successful.

Southport Medical Society.—The usual monthly meeting of this society was held on Feb. 14th.—Dr. Robert Harris was elected to the office of President, the post being vacant through the death of Dr. H. H. Vernon. A vote of condolence with the wife and family of the late Dr. Vernon was unanimously passed.—Dr. J. C. Russel made a communication on the Spasmodic Structure of the Œsophagus, and he showed an Air Dilator which he had invented for the treatment of this condition and had found to prove very successful.—Mr. J. Forrester Wood showed a case of Compound Depressed Fracture of the Skull with trephining.—Dr. Stopford Taylor gave an interesting lantern lecture on various Skin Affections, with practical comments. About 60 lantern slides were shown and the demonstration was much appreciated by the members.

Pathological Society of Manchester.—A meeting of this society was held at Owens College on Feb. 4th, Mr. Thorburn, the President, being in the chair.—Dr. Nathan Raw opened a discussion on the Pathology of Pneumonia, with Special Reference to its Bacteriology. He reviewed at length the various theories which had been put forward and the supposed influence of chill in the causation of the disease. He said that the evidence was all in favour of pneumonia, being a specific disease due to a micro-organism, the diplococcus of Fränkel, and that the treatment of the future would be antitoxic.—A number of members took part in the prolonged and interesting discussion which followed and Dr. Raw exhibited a large number of specimens.—Other preparations were shown as card specimens.

Wigan Medical Society.—The annual general meeting of this society was held on Feb. 15th, when the following office-bearers for the ensuing year were unanimously elected:—President: Mr. R. H. Cowan. Committee: Mr. R. H. Cowan (President), Mr. Luther Cooke (ex-President), Mr. C. M. Brady, Mr. W. Mitchell Roocroft, Dr. J. Blair, Dr. M. Benson, Dr. R. P. White, and Mr. C. R. Graham. Honorary treasurer: Mr. E. H. Monks. Honorary secretary: Mr. W. Berry. The annual dinner followed.

Reviews and Notices of Books.

A Text book of Diseases of the Nose and Throat. By D. BRADEN KYLE, M.D., Clinical Professor of Laryngology and Rhinology, Jefferson Medical College, &c. London: Rebman, Limited. Philadelphia, U.S.A.: W. B. Saunders. 1899. Pp. 646.

THIS is a well-bound and comprehensive book of over 600 pages. 340 pages are devoted to diseases of the nose and naso pharynx. This part of the subject is very full and elaborate and the classification adopted by the author is original. The book opens with a short chapter on the Anatomy and Physiology of the Nose, and we are glad to find that the author is brief on this part of the subject, which can be studied so abundantly elsewhere. The examination of cases of nasal disease is excellently described and Fig. 14 shows more accurately than is usual in works of this kind the appearances seen in the rhinoscopic mirror on posterior rhinoscopy. The author speaks highly of posterior illumination in diseases of the nose and figures several novel "atomizers" which he has found useful in his practice. He discusses the subject of nasal bacteria, but concludes that they play quite a secondary part in producing disease. This opinion is well expressed and is of some value. The classification of the varieties of rhinitis seems unduly elaborate and we venture to think that a clinical observer would have some difficulty in being able to differentiate the various affections of the mucous membrane of the nose pathologically described. So far as we can judge, this part of the book is free from speculative methods of treatment. In the treatment of atrophic rhinitis and ozæna the author dwells upon the methods and importance of methodical cleansing of the nasal cavities and does not advocate the use of the curette or operations upon the turbinals. Throughout the book an attempt is made to base diagnosis and treatment upon pathological alterations. In some places the descriptions are hardly clear and perhaps might not meet with general acceptance. On pages 51 and 52 we read as follows:—

> "Where the floor of the nose or superior maxillary bone is thin from deficient breathing in early childhood or other cause, the terminal nerve filaments going to the root of the tooth course superficially along the floor of the nose, and in cases of deflected septum, where the deflection is close to the floor of the nose, with redundant tissue, the inflammatory process injures the nerve roots and causes devitalised teeth, or may ulcerate and produce a sinus, discharging around the tooth, simulating *pyorrhœa alveolaris. I have observed a* number of such cases."

The classification of tumours and growths of the nose is founded on general principles. In our opinion the author hardly lays stress enough on the practical difficulties met with in cases of inveterate nasal polypi and especially the co-existence of necrosis and sinus suppuration. He opposes the after-treatment of removal of polypi by the galvanic cautery and caustics, in which he would not receive universal support. Many authorities in this country look upon the persevering use of the cautery or such applications as chromic acid as very essential in the permanent eradication of polypoid growths.

The diseases of the naso pharynx are well given. We think that the various modes of operating for adenoids might with advantage have been more fully given and the all important subject of the administration of anæsthetics in this and similar operations is, we consider, too shortly dismissed. A good account of the difficult subject of sinus suppurations is to be found in this book. Opening the sphenoidal cells by a sharp instrument guided by the rhinoscope must be a surgical proceeding to be performed by the very few. On the diagnosis of frontal sinus suppuration the author does not dwell upon catheterisation through the infundibulum as being of much value and trans illumination is at best a very poor guide. A short but useful chapter is introduced on Related Conditions of the Eye and Nose in Disease.

The section on Diseases of the Larynx is full and accurate. Separate chapters are devoted to Intubation and Tracheotomy. Professor Keen contributes a short article on Laryngeal Operations by External Incision and advocates the Trendelenburg position. The work concludes with a copious index. Throughout we find many suggestions for treatment, therapeutical and otherwise. Some of them are novel, and the book bears the stamp of originality and experience.

The volume is illustrated profusely by 175 illustrations, 23 of which are coloured. Most of these are new and some are exceedingly good. As instances we may mention "Adhesions of the Soft Palate to the Pharynx" (Fig. 121), and "Enlarged Tonsils" (Fig. 126). The coloured plates of sections of adenoids are beautifully executed. The book is well printed and got up and the misprints are very few. It is a useful and complete treatise and will doubtless be read by those practising in this class of medical and surgical diseases.

Insects. By D. SHARP, F.R.S. Being Vol. V. (in part) and Vol. VI. of "The Cambridge Natural History." Edited by S. F. HARMER, F.R.S., and A. E. SHIPLEY, M.A. London: Macmillan and Co. 1895 and 1899. Price 17s. net. each vol.

THIS bulky work is the most comprehensive *modern* treatise upon insects in the English language with which we are acquainted. Its bulk is due to the industry and extremely wide knowledge of its author, and not to that unwholesome substance known as padding. Dr. Sharp is eminently qualified to write upon this subject, being one of our best known entomologists; and he has proved that an entomologist whose main repute is derived from contributions to a single group does not always go through the world, as the late Professor Chandler of Oxford once said in our hearing, "seeing only beetles." Although Dr. Sharp occupies to the full, even increasing their dimensions here and there by the use of small type, more than 1100 pages it cannot be said that either he or his editors have been without a due sense of perspective. As the author tells us in his very first sentence, "Insects form by far the larger part of the land animals of the world, they outnumber in *species* all the other terrestrial animals together, while compared with the vertebrates their numbers are simply enormous." In a more striking phrase Dr. Sharp observes that "the larger part of the animal matter existing on the lands of the globe is in all probability locked up in the forms of insects." With such an immense mass of matter before him it is pleasing, but not unexpected from what we know of the author, to find that he abhors all the twaddling tales which have collected round the natural history of insects more than round any other group of animals. It must not be imagined from this that the author disdains what is called "natural history" by the reading but non expert populace and "biologie" by the Germans. There is much of interest told about habits and ways of life, particularly among those astounding "*intellectuels*" wasps, ants, and bees. We can commend his account of ants as one of the best and most comprehensive of the sections dealt with in the two volumes. Dr. Sharp seems to have omitted nothing upon which we have sought information by the help of an apparently very detailed index. Recently the myth of the ancients concerning the propagation of bees has been dealt with by a well known student of insects, Baron Osten Sacken. Most of our readers will recollect in the Fourth Georgic the account of the generation of bees from the well "tunded" carcass of a young bull whose horns have just begun to sprout. "When the meadows are enamelled with their earliest flowers" worms appear in the carcass from which bees are born. Now it appears from the highly reasonable explanations of the entomologist whose name has just been cited that what the ancients mistook for bees were certain flies belonging to the genus eristalis, which are singularly like bees, and of which one species, the drone fly, must be familiar to most persons. This opens up an interesting question which baffled Kirby and Spence, though some of our more modern theorists appear to find no difficulties at all in the explanation. This and some other flies have the most accurate likeness to bees and to wasps in various non-essentials. No naturalist could, of course, confuse them, but their general aspect is un-fly-like and very bee- or wasp like. One genus (volucella) has the daring habit of entering the hives of bees and the nests of wasps and there depositing its eggs. It needs no theory at all to emphasise the remarkable immunity which both the flies and their offspring secure at the hands, or perhaps rather jaws, of the hymenoptera. It has been suggested—indeed, there has been a tendency positively to assert—that the likeness of the flies to bees allows them to evade the attentions of their involuntary hosts. This is an example, only too frequent in the views of those who deal with the singular phenomena commonly called "mimicry," of rash generalisation without an adequate basis of fact. "There are no facts," observes Dr. Sharp, "to support any theory on the subject." The flies get there—that is all we know. That bees and wasps would be perfectly capable of ejecting, and willing to eject, them seems obvious when we reflect upon the accurate senses which enable these hymenoptera to distinguish the inmates of another nest, but they do not. Dr. Sharp thinks that the fly larvæ in question play the useful part of scavengers in the nest.

From flies to fleas is not, according to Dr. Sharp, a great jump. The latter were at one time made into a separate group called aptera. This name is at present reserved for two curious groups of insects—the collembola and thysanura—which are regarded as representing more nearly than any living forms the ancestral types of insect life. The fleas are simply flies degraded through perpetual parasitism. 100 species exist, so that parasitism is here, as in so many other cases, e.g., the tapeworms, productive of much variability of animals. The common flea of man, pulex irritans, is found all over the world. Indeed we have reason to believe that the only animals which are true cosmopolites are man and his parasites. It is a curious fact that monkeys possess no fleas save in exceptional cases of weakness or illness. This immunity seems to be due to the habit that these creatures have of perpetually searching for supposed residents on their skin.

Readers who are less interested in anatomical and embryological details than in gossipy tit-bits will find much to allure them in this book. Every summer, the last for instance, there is much correspondence in the newspapers concerning "mosquitos." "Although there are few insects," writes the author, "more often referred to in general literature than mosquitos yet the ideas in vogue about them are of the vaguest character." The main idea in the mind of the public appears to be that the mosquito is a poisonous exotic insect which occasionally ravages this country. As a matter of fact there are ten indigenous species in this country of which culex pipiens is *the* mosquito *par excellence.* It is a common species in central and southern England, Dr. Sharp tells us. It also exists abroad and is "one of the most troublesome mosquitos of East India" There are many interesting facts and not a few theories about this widely spread pest. Those who have been in the extreme north of Europe should know and dread it well; there it abounds on account of the abundance of water which is essential to its well-being as the eggs are laid in water and the larva lives there. Millions of these flies exist who can have had no opportunity of tasting human blood; yet with unerring instinct they will fasten upon the first man who breaks into their solitude and literally "tap his claret" with precision. Mr. Hudson has pointed out this singular case of instinct which is the less intelligible as they appear normally to feed upon the juices of plants. Another puzzling fact is that the female, who alone bites, injects a poison into the wound; this seems to be a purposeless form of irritation. It is, however, suggested that the irritant fluid is for the purpose of preventing the coagulation of the "plant juices during the process of suction." To the physician this group of flies is becoming of especial importance because of their influence on dissemination of disease.

Probably the majority of those persons who are interested in insects have a special leaning towards the butterflies and moths. They will find all reasonable curiosity concerning the ways of life of these creatures satisfied in the volume before us. Dr. Sharp adheres to the now rather old-fashioned division of the lepidoptera into butterflies and moths. There are not, however, two such opposed groups, though it is true that "all lepidoptera that are not butterflies are heterocera (i e., moths)."

To the inexpert mind anything that flies by night and is dully coloured is a moth, while day-flying habits and brilliant colouration are supposed to denote a butterfly. This, of course, will never do. Many moths rival the most gorgeous of butterflies in their hues, while some of the danaidæ (we think) are often found in the early morning glued to lamp-posts like "strayed revellers" of another species. Some of the more senescent and obsolescent theories upon animal colours have been based upon these insects. Dr. Sharp says of the puss moth and the views about its larva that it realises the dictum of D. O'Phace, Esq.:—

> "Some flossifers think that a fakulty's granted
> The minnit it's proved to be thoroughly wanted."

This caterpillar has a pair of "tails" from which can be protruded flagella which whip about in a threatening manner. It is believed by some that the object of these is to lash off prowling ichneumons. But it is an expensive method, if it be so, of producing an apparently negative result; for these larvæ are quite as much "ichneumoned" as others. Then it has a terrifying attitude; but we have yet to learn that little birds are frightened, like little boys, by having faces pulled at them. Dr. Sharp treats these matters with a good-humoured note or two, which form, as is right, but a minute fraction of the book. It will have been gathered, we hope, that this is a book abounding in facts well and clearly put, which should be in the hands of everyone devoted at all to insects. Its handiness for the student of this group is further increased by a very large number of illustrations in the text, a large proportion of which are quite new and specially designed for this work.

The Story of Life's Mechanism: A Review of the Conclusions of Modern Biology in Regard to the Mechanism which Controls the Phenomena of Living Activity. By H. W. Conn. London: George Newnes, Limited. 1899. Pp. 219. 50 Illustrations. Price 1s.

The "Library of Useful Stories' continues to grow, the subject of this review being one of its latest additions. As its sub-title indicates, this little book considers some of the problems presented by modern biology.

The work is divided into an introduction and two parts. The introduction is mainly historical, dealing with various discoveries which have had an important influence upon modern lines of thought. Part 1 is divided into two chapters, the first of which defines a machine, and then enters into a comparison between such a mechanical contrivance and an organised body. It then passes on to the consideration of the chief vital functions and other matters. Chapter II. deals with the cell and protoplasm, including a description of the phenomena attending karyokinesis, fertilisation, &c. Part 2 contains but one chapter which, among other matters, discusses evolution, reproduction, heredity, and variation.

On the whole the book is distinctly good; there are a few points, however, which might be improved. We refer more especially to the illustrations. Firstly, some are, in our copy at least, somewhat indistinct. Then, again, a botanist would hardly consider Fig. 10 to represent a typical longitudinal section of a root apex. The impression gained from Fig. 12, illustrating "plant cells with thick walls," is that the cells have thin walls and the protoplasm has shrunk, thus giving the appearance of clear spaces between the cell walls and contents. A wrong impression is so easily obtained by the general reader that too much care cannot be bestowed on a popular book of science, especially as regards the illustrations, and this being so it would have been as well to have stated what particular animal or plant each figure illustrates; this has been done in some cases, but not in all.

On page 91 it may be read that "Schultze experimented with this material by all means at his command, and finding that the cell substance in all animals and plants obeys the same tests reached the conclusion that the cell substance in animals and plants is always identical." Surely it was Cohn who, in 1850, first enunciated the fact that the sarcode of the zoologists was identical with the *protoplasm* of Von Mohl.

The book is very clearly written and will give those who desire it an excellent conception of some of the problems which are engaging the attention of biologists at the present time.

JOURNALS.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXV., No. 3. London: C. J. Clay and Sons. Feb. 2nd, 1900. Pp. 54. Price 4s.—The articles contained in this part are seven in number. The first is by W. H. Thompson, M.D., and is a continuation of his researches on the Influence of Peptone and Albuminoses on the Urinary Secretion. He concludes from his experiments that at least 60 per cent. of peptone or proteose introduced directly into the circulation is retained in the body; that a larger proportion of deutero-proteose, of purified amphopeptone, and of antipeptone appears to be retained than of the primary proteoses, and that it is probable that the proteoses are held in combination with one of the globulins of the blood plasma as proteose globulinates. 2. R. E. Lloyd, B.Sc.: On Chromatolysis in Deiters' Nucleus after Hemisection of the Cord. The investigation tends to show that after a unilateral lesion of the cord involving the antero lateral descending tract most of the cells of Deiters' nucleus undergo chromatolysis. The inference drawn by Mr. Lloyd is that the fibres of this tract take origin in Deiters' nucleus and not in the cerebellum. 3. H. H. Dale, B.A.: On Some Numerical Comparisons of the Centripetal and Centrifugal Medullated Nerve Fibres arising in the Spinal Ganglia of the Mammal. Mr. Dale's observations were chiefly made on the cat. He finds that there are a few more medullated fibres in the trunk than in the nerve roots, the excess consisting probably of fibres which pass the trunk by way of the grey portion of the ramus communicans and end in connexion with the vessels or other tissue of the ganglion. The appearances presented by the nerves as seen in section are illustrated in a plate which accompanies the article. 4. David Fraser Harris, M.D. Glasg.: On the Pressure-filtration of Proteids. The experiments show that the commonly occurring proteids pass through the pores of a Chamberland filter in the interior of which the pressure is considerably below that of the atmosphere. Caseinogen in milk, however, and Grübler's caseinogen dissolved in lime-water do not yield pressure filtrates. 5. D. Noël Paton, M.D. Edin., J. Craufurd Dunlop, M.D. Edin., and R. S. Aitchison, M.D. Edin.: Contributions to the Study of the Metabolism of Phosphorus in the Animal Body. One of the conclusions arrived at by the authors of this article is that in the normal condition, with the animal (dog and goat) in phosphorus equilibrium, the absorption and excretion of the phosphorus by the intestine are equal. 6. John Haldane, M.D. Edin., F.R.S.: The Supposed Oxidation of Carbonic Oxide in the Living Body. 7. John Haldane, M.D. Edin., F.R.S.: On Cyanmethæmoglobin and Photomethæmoglobin. These are shown to be identical.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., aided by ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S., with Lithographic Plates and Engravings on wood. London: J. & A. Churchill. New Series. No. 169. Vol. XLIII. Part I. February, 1900. Pp. 193. Price 10s.—The contents of this number are—1. James P. Hill, F.L.S.: Contributions to the Embryology of the Marsupialia, parts 2 and 3, with two plates. The fœtus here described is that of the Perameles or Bandicoot, the early stages of the embryology of which are given in some detail. 2. H. M. Bernard, M.A. Cantab.: Studies in the Retina; Rods and Cones in the Frog and in some other Amphibia. In the frog Mr. Bernard finds that there are two kinds of simple cones—"the one is short without a basal vacuole, and the other about one-third longer and with a basal vacuole" which may be very much distended. Minute measurements are given of these structures and of the rods and he has satisfied himself that the cones in the amphibia are merely stages in the development of the rods, a view which, if corroborated by further research, must have important bearings upon the physiology of the retina. Some excellent drawings accompany this memoir. 3. G. S. West, B.A.: On the Sensory Pit of the Crotalinæ. This pit is situated near a line drawn from the eye to the nostril and is divided into two chambers by a thin partition, of each of which a precise description is given. The walls of the cavities are freely supplied by branches of the fifth pair of nerves and are highly vascular. No suggestion is made as to the probable use of the organ. The article is illustrated by a plate with many drawings. 4. J. W. Jenkinson, M.A. Oxon.: A Re-investigation of the Early Stages of Development of the Mouth. This is a polemic dealing with recent views on the earliest stages of the development of mammals and he remarks that the phenomena which we observe in the early ontogeny of the mammalia are, in his opinion, absolutely *sui generis*. 5. W. Blaxland Benham, D.Sc.: On the Structure of the Rostellum in Two New Species of Tapeworm from Apteryx. 6. The remaining article is on the Habits and Early Development of Cerebratulus Lacteus (Verrill), by Charles B. Wilson. The cerebratulus is a Nemertean found along the entire Atlantic coast from Florida to Massachusetts Bay at, and just above, low-water mark. They are active at high tide and are carnivorous. The memoir is accompanied by three plates with numerous drawings.

VICTORIA HOSPITAL, SWINDON.—The annual meeting of this institution was held on Feb 10th under the presidency of Captain F. Goddard. The report showed that 225 patients had been admitted during 1899 and that there remained a favourable balance of £146. The chairman announced that he had given the land, which was said to be worth £300, for the enlargement of the hospital grounds. Captain Goddard had previously also given the site upon which the hospital stands.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 24, 1900.

GREAT BRITAIN certainly has her hands full at the present moment, but we very much mistake if she will not find means of extending help to India, where a large portion of the population is affected by the famine. The calls of the war are great and will be greater. Even if fighting comes to an end sooner than we expect it to do there will be an addition to our expenditure for some time to come which will necessitate a material curtailment of our luxuries. Disabled men, fatherless children, and widows will appeal to us, as they have never done before, and we must meet the appeal more generously. But the famine in India is our concern too. The scale of it is unprecedented and it is still widening. The latest telegram from the Viceroy reports, "Famine distress still steadily on the increase," and we must listen to such a message.

It is difficult for us in England to realise the facts of these large Indian famines and the wide misery entailed. It is only three years since a famine in very much the same North-Western districts prevailed when, it is said, the hunger was so extreme that women ate their own children. (This is not an old wives' tale.) The area of the present famine is wider and the numbers affected are believed to be larger. The famine area in the former famine was three times that of the British Islands, now the area is said to be more than four times the size of these islands and the population affected to be more than 75 000,000. We may well be proud of the brightest jewel of our Imperial crown, but this feeling must be tempered with a strong admixture of responsibility. The poverty of the great mass of the Indian population, their existence on the very verge of starvation and at the mercy of the clouds of heaven, place us, their rulers, at all times *in loco parentis*. methods of help must always be ready if the people are not to be swept off the face of the earth by millions. We have long recognised this obligation to the races of India and it is not a little to the credit of our rule that the mortality from famine has been greatly reduced. The Viceroy in his last speech, pleading eloquently for the help of private generosity, calls attention to the grateful fact that actual mortality is now largely repressed. This is undoubtedly a great improvement, but short of actual mortality there is an evil that is nearly as sad for the people—viz, a physical depression that deprives life of all power and of all pleasure—that makes existence a burden and renders the half-alive subject an easy prey to disease. The British rule in India is one of the most beneficial recorded in history, but it has mightier work still to achieve in raising the physical and social condition of the people. We see from week to week the painful proofs of the persistence and growing prevalence of the plague in spite of all sanitary and medical measures, and it cannot be doubted that one chief reason of this is the inherent physical weakness of the population, due largely to poor powers of resistance, the result of inadequate nourishment. The appeal of the Viceroy must be answered generously and promptly. The real stay of the Indian Government and the real security of our hold on India is the sympathy of the people of the British Empire. The Indian peoples know of this sympathy and return it. Of all the gratifying things which qualified our grief during the opening scenes of the South African war none has been more significant than the loyalty of the Indian princes and of the Indian people. The princes have given their money and the people have given their prayers for our success. Admiration for the EMPRESS and gratitude for the beneficence of her rule have found the most practical expression. We must make it clear that these sentiments are appreciated, and that our ordinary sense of responsibility for the welfare of the teeming races of our fellow-subjects in India is much accentuated by their splendid liberality and loyalty in connexion with the war in South Africa.

There is one other fact which may well stimulate us as a Christian nation. It was pointed out by English missionaries in the Indian famine of 1897 that the Hindus were most generous in their charity towards the Famine Fund, though not 10 per cent. of those relieved were of their faith. We cannot do less than show them that our religion, too, bids us "give our bread to the hungry." Very little money goes a long way in the purchase of food in India. It is said that a penny will give a meal to a man and that half-a crown will supply a child's food for a month, though in times of scarcity prices rise. We have not to do with a pampered population. But one word of caution seems called for here. The amount of food, or its equivalent in money, absolutely necessary to support life must not be calculated too nicely. In the famine of 1897 some of the zemindars and farmers complained that the wage given on the relief works was more than could possibly be earned in agricultural labour, and that it would tempt the people away from the country districts to the relief works. The men's daily wage was thereupon reduced from about 2*d.* to 1½*d*, and the women's from 1¾*d.* to 1¼*d.* The result was that thousands of these unfortunate workers went home to die, being unable, at the famine price of grain, to keep body and soul together, much less to work. Here was failure to save life, but more is expected of England than the mere prevention of death from starvation. The Government of India is committed to that measure of relief, but help is needed to reinstate the destitute and to give them a fresh start with a brighter hope for the future. Therefore a very large sum of money is wanted, and in spite of all the urgent calls upon our resources that money must be found.

◆

IN the social history of the nineteenth century there are few more conspicuous changes than that which is marked by the rise of the medical profession as a whole. Great physicians and surgeons there have always been who for their prominent skill and knowledge if not for their qualities as men of the world or of the court, have risen to be the trusted friends and advisers of the leaders of the country, but until recent times these have been the brilliant exceptions, the lustre of whose position served only to show by contrast the dull position in which their professional brothers worked Those who practised medicine, as distinguished from surgery, were no doubt from mediæval times onwards, in a better position, but even the physicians were thought to be entitled to small consideration Gradually—and contemporaneously with the growth of knowledge and of respect for men working at other professions than those of the Church, the Army, and the Navy—the medical profession has attained to a certain position in the public eye, and this has been accomplished by constantly raising the standard of education required of its members thus fitting them for the increased trust that should be earned by their increased responsibilities A hundred years ago who would have dreamed of a surgeon holding the position now held with universal acclamation by Lord LISTER' The dreamer could have as little imagined the surgical successes that owing to Lord LISTER'S discoveries, have become common occurrences of our everyday work

With this general advance in the status of the medical profession there has come, partly as cause and partly as effect, a widespread desire among its members for a share in those interests and activities which used to be found only amongst our leading medical men This is proved by glancing at the number and condition of medical societies as they were and as they are At the beginning of the century here and there a few enthusiasts, their energies concentrated perhaps around some great physician or surgeon banded themselves together to meet at stated intervals for the discussion of professional matters Thus arose under the auspices of JOHN HUNTER and FORDYCE the Society for the Promotion of Medical and Surgical Knowledge, dissolved in 1818 only when it was more than adequately replaced by the Royal Medical and Chirurgical Society founded in 1805, and by the Medical Society founded in 1773 At that time such societies were to be found only in the great cities—rarely even there—and were by the difficulties of locomotion greatly limited to the quarter of the city within which the few members lived How complete is the difference between such a state of affairs and that which obtains to day In London it would tax the memory of the medical resident to reckon up the medical and surgical societies that are flourishing around him, while every large town in the kingdom has its two or three such associations and no suburb or provincial district is without at least one rallying point for local practitioners of medicine

The value of such institutions is scarcely to be overrated, particularly their value to the general practitioner Everyone in the course of his practice comes sooner or later upon cases which leave him in doubt even after the most careful observation and deliberate reflection If the patient is wealthy it is easy enough for his medical attendant to recognise that two heads are better than one and to call in the opinion of some one who from greater experience or more special attention to just the class of case in question is likely to throw light upon the matter Suppose, however, the patient cannot afford the expense of a further opinion, and yet is not suitable or does not wish for hospital treatment To bring such cases before the local medical society is a ready help to the medical man and a useful course for his patient Not only is the medical man in charge almost certain to profit by the new points of view from which his fellows will see the case, but also the mere fact that he has to present the case to them in a clear, comprehensive and comprehensible manner causes him to think over signs and symptoms afresh from the beginning, when he will definitely formulate his opinions in the matter in a way which he may not have been led to do before. But for medical societies to be of the fullest use there is one condition to be observed, the meetings must be those of equals with equals If a man is overshadowed by the presence of many whose knowledge and opportunities are greater than his own, he will fear to expose his comparative weakness, he will get into the way of going only to listen, and he will never reap the benefits that medical societies should afford to all their members For perhaps their greatest benefit of all is the practice that medical societies afford to their members in the art of public speaking, an art which no medical man should be without, though one in which he has little chance of improving himself except at these meetings It is not sufficient to know, a medical man to be truly useful to his fellows should be able to impart his knowledge Again, it is a great thing to feel the value of good advice, but good advice cannot be obtained unless the points of difficulty are succinctly stated We regard the activity that is now displayed in the provinces in the founding of medical societies of excellent omen for the medical profession Properly treated these societies should form not only exchanges of professional knowledge but centres of professional *esprit de corps*

◆

UP to noon on Wednesday last we had received answers from 6299 English practitioners in answer to our three questions (1) Are you in favour of legislation for the regulation of the practice of midwives? (2) Are you in favour of the Bill now before the House of Commons? (3) Are you indifferent in the matter? This figure represents of course not quite one third of the constituency to which we appealed and we may fairly expect to receive many more replies At the same time enough answers have been sent to us to show clearly what is the view of the medical profession, for we may take it for granted that the one third or so who have replied are fairly representative of the whole number in their views 1617 English medical men then, consider that no legislation is required for the regulation of the practice of midwives, and of these 1500 add that they are opposed also to the Bill now brought before the House of Commons by Mr TATTON EGERTON 121 medical men are opposed to Mr TATTON EGERTON'S Bill but do not state whether they are opposed to legislation generally 1323 are opposed to the Bill, while they desire to see legislation for putting down many of the practices now in vogue among unqualified persons as a consequence of the somewhat ineffective operation of the existing Medical Acts. These medical men desire legislation, but legislation of an opposite sort to that offered to them by the Midwives Bill. 433 medical men are in favour of legislation for the regulation of the practice of midwives but not in favour of the Bill now before the House of Commons. 1311 medical men are in favour both of legislation for the regulation of the practice of midwives and of the specific Bill. 698 medical men did not content themselves with simply saying "Yes" or "No" to the questions, but wrote letters explaining their views. We have submitted their replies to a somewhat rough analysis. 445 were opposed either totally or in detail to Mr. TATTON EGERTON'S Bill, while 143 were more or less in favour of it, and the remainder could not be classified. 596 medical men frankly expressed themselves as indifferent to the whole matter. By our poll of the profession, as far as it has gone, we have accumulated great knowledge of what English medical men really think on the question in general, but at the present time the particular Bill before the House is all that we are concerned with. It will be seen that of 6299 medical men who have expressed their views to us 1311 only are in favour of the Bill. These figures cannot be without their influence in the House of Commons, but before the Bill is read a second time we hope that we shall be able to place before the legislature the opinion of a larger proportion of the medical profession in the country. We repeat our request for replies to our circular letter, which should reach us absolutely not later than Monday next, Feb. 26th.

Annotations.

"Ne quid nimis."

THE STATUTES OF THE RECONSTITUTED UNIVERSITY OF LONDON.

THE statutes recommended by the Commissioners under the University of London Act, 1898, have been laid before both Houses of Parliament and will remain there for 40 days previously to their becoming legal enactments. Opposition will be no longer offered to the formation of a great metropolitan university in London, although this desirable idea has been so persistently dogged by narrow and sectarian opposition in former years. We still hesitate as to the practicability of two schemes running side by side for internal or collegiate students on the one hand and for non-collegiate students on the other; but at any rate the two classes are to be placed under different jurisdictions The authoritative power in the new University will be the Senate of 56 persons (all told), but the really influencing body will be the Academic Council of 20. Their function is advisory only, but we cannot fail to see that this council must materially influence every decision of the Senate, at least so far as the education and examination of internal students are concerned. The external students in arts, science, and laws will be educated anyhow and anywhere, but will pass examinations on lines mainly laid down by the 16 members of the Senate appointed by Convocation. The statutes say that the Senate, while prescribing courses of study for internal students, will ensure in each case an academic training of adequate breadth and duration, and will endeavour to allow the students a wide option in the choice of study. We are anxious to see how the Senate will reconcile this assurance with the expressed intention that degrees conferred upon internal and external classes of students shall represent as far as possible the same standard of knowledge. Fortunately there are no stringent provisions as to the education or examination of the medical students, and powers are granted to the Senate to make arrangements with the Royal College of Physicians of London and the Royal College of Surgeons of England, or either of them, to conduct jointly with the Senate examinations in such portions of the subjects included in the course of study for a medical degree as may be agreed upon between the Senate and those Colleges. The Senate can make similar arrangements with other corporations and institutions holding professional examinations in subjects included in other courses of study, and we hope to hear less in the future of unnecessary examinations and re-examinations.

THE LAW OF THE COMPOUNDED DRUG.

A RECENT appeal in a case under the Sale of Food and Drugs Act of 1875 is of interest, not only because the purity of drugs sold is a matter of public importance but also on account of the manner in which the difficulty arose. This difficulty, it may be said at once, was one for which the legislature is primarily responsible. It must in the case now referred to and in others have caused avoidable expense, and it might have been removed many years ago. A person had been prosecuted under the 6th section of the Act for selling as camphorated oil that which contained a less proportion of camphor than is prescribed by the British Pharmacopœia. The 6th section of the Act runs as follows:—"§ 6. No person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, under a penalty not exceeding twenty pounds. Provided that an offence shall not be deemed to be committed under this section in the following cases; that is to say ...... (3) where the food or drug is compounded as in this Act mentioned." The seller of the camphorated oil had succeeded in convincing the magistrate that he came within the exception quoted and that the summons against him should have been not under the 6th section but under the 7th section of the Act, the only other section in which mention is made of compounded drugs. This section runs as follows: "§ 7. No person shall sell any compound article of food or compounded drug which is not composed of ingredients in accordance with the demand of the purchaser under a penalty not exceeding twenty pounds." It will at once strike anyone reading this section that it must have been intended to refer to cases where the prescriptions of medical men are presented to be made up, and this view is, no doubt, the correct one. In the case under consideration the Divisional Court decided that the prosecution had been properly instituted, as whatever meaning section 6 sub-section (3) might bear with relation to section 7, the offence before them was equally within section 6. The judges seem, at all events, to have found a way out of a difficulty with some ingenuity. The true meaning of sub section (3), quoted above, was suggested to their lordships, but they pointed out that although it seemed pretty clear from the obvious construction of the sections that something had been omitted they could not take cognisance of extraneous information with regard to this. As a matter of fact, when the original Bill left the House of Commons it contained a section which ordered that all compounded drugs sold should be combined is the preparation prescribed in the British Pharmacopœia. The House of Lords struck out this section but omitted to strike out the sub-section (3) which referred to it, and so it alone, so that sub-section (3) was consequently left without meaning until a strained one was sought to be found for it by bringing it into relation with section 7. When we add that the case of White v. Bywater[1] in 1887 decided that a customer who had asked for tincture of opium was entitled under the Foods and Drugs Act to have it sold to him of the standard provided by the Pharmacopœia it will be seen that the interference of the House of Lords with the Act was, in this detail at all events, not attended with happy results. It is also a matter for regret that the legislative machinery still is so cumbrous as not to be able to rectify quickly and easily mistakes made in its output. That draftsmen should occasionally make slips is not to be wondered at, particularly when we consider the unwieldy, complicated, and often unintelligible system that has grown up of legislating by means of cross references to other Acts already in existence. This system once had as a result a somewhat quaint mistake. In the Destructive Insects Act of 1877, framed chiefly to protect the agriculturist against the ravages of the Colorado beetle, there are sections which for the purposes of certain matters of procedure incorporate the Contagious Diseases (Animals) Act, 1869, by name. As is usual the numerical description of the Act is given in the margin. It should have been 32 & 33 Vict. cap. 70, but there were two Contagious Diseases Acts passed in 1869, one of which related to the lower animals while the other did not, and the draftsman by mistake took the wrong one. Consequently if anyone turns to an original copy of the Destructive Insects Act he will find marginal reference to 32 & 33 Vict. cap. 96, the presumable effect of which, if it were literally carried out, would be to subject the Colorado beetle to periodical medical examination by a visiting surgeon, with the possibility of detention in a certified hospital. We believe that in later editions of the Act this slip was summarily corrected. The alteration of the Food and Drugs Act would presumably require an Act of Parliament.

APPLIED SCIENCE IN MODERN WAR.

ONE of the notable circumstances connected with the present war in South Africa has been the wide and varied application of the results of modern science in regard to it. Setting aside altogether those of a purely military character, such as arms of precision and rifled and quick-firing guns, the use of which has demonstrated the enormous advantages they are capable of conferring in defensive warfare, there are many other directions in which the influence of applied science may be recognised. We perform nowadays much of our scouting by balloons and transmit the result of observations obtained from an altitude and supplemented by the aid of field-glasses to troops advancing or operating on the field of battle. The best telescopes and an abundance of field-glasses are always in requisition; the latter may be said to form an essential in the list of personal field equipment. By means of wireless telegraphy and with the aid of kites communication has been successfully established between various stations occupied by British troops in the theatre of war in Africa. As regards our sanitary and medical services, a stricter application of the rules of practical hygiene has been attended with a remarkably progressive improvement in the health of our soldiers in the field in the successive expeditions which have taken place since the time of the Crimean war. Infective wound diseases, which used in past times to prove a veritable scourge among our wounded in military hospitals, have been practically banished from them by universal and scrupulous attention to cleanliness, by the rigid use of antiseptic dressings in wounds and injuries, and by the performance of all operations upon patients under anæsthesia; while the use of the Röntgen rays has enabled us to detect the presence and exact site of any missile or foreign body. The various ingenious probes for the detection of bullets embedded in the tissues are no longer seen in military surgery but have been relegated to the surgical museum among other relics of past art. And these are only a few of the innovations for which applied science is responsible.

THE FERTILITY AND STERILITY OF NATIONS.

THE relative fertility of different nations and races is a problem which, despite its absorbing interest, has hardly received at the hands of science the attention it deserves, for although the passing away of nations and of races is a matter of history, but little inquiry has, as far as we are aware, been directed towards determining the causes which in one or another instance have been instrumental in bringing about the decay of reproduction. As with families so with nations, fecundity is in the long run the factor which determines their more or less indefinite survival. In the cases in which aborigines have been brought into contact with highly civilised nations a diminished fertility has apparently accounted for the disappearance of the natives, and the now vanished Tasmanians and the rapidly falling Australian aborigines may be quoted as instances in point. So, too, with the Maoris of New Zealand there would appear to be indications that in contact with a European people they cannot flourish. Amongst, however, civilised nations limitations to their increase would seem to be brought about by the indirect effects of social and economical forces resulting in postponement of marriage until a relatively later period, by an unwillingness to undertake the responsibilities of parentage, and by other complications in the social system of a nation all making towards national sterility. An article by Dr. Drouineau in the current number of the *Revue d'Hygiène et de Police Sanitaire* based upon the recent report of M. Fontaine, the director of the French Office of Works, is full of interesting information on the fecundity of France. During 1898 the birth-rate of France was 22·1 per 1000, as against a rate of 22·4 for 1897, while the death-rate for 1898 was 21·2 per 1000, in place of 19·6 for the preceding year. There is, in fact, as Dr. Drouineau points out, a marked tendency at the present time in France for the curve representing the birth-rate to meet the curve representing the death-rate, the former falling, the latter rising, and although during 1898 there was an actual excess of 33,860 births over deaths the author of this paper views the future with no little disquietude. When, too, the figures for the several departments are gone into it transpires that during 1898 there was an excess of deaths over births in no less than 43 departments and an excess of births in only 30 departments, the departments presenting this excess of deaths remaining the same year after year. In 1898 there were nine departments in which the birth-rates exceeded those of the previous year while in 10 the rates remained stationary. Amongst those departments which yielded the highest birth-rates during 1897 there was a marked falling off in 1898, a phenomenon, as the author points out, of particular gravity. If, he says, the fecundity of these departments becomes feebler year by year the results will be disastrous, more particularly if, as is the case, the mortality remains relatively high. The birth-rate exceeded 23 per 1000 in 22 departments and was below that figure in 21 departments, and, as regards these latter 21, we note that the rates ranged between 18·9 to 14·5 per 1000. In 13 departments the death-rate was above 23 per 1000, the highest being 25·4, while among those departments of small mortality the rates ranged from 18·9 to 15·8 per 1000. The influence which immigration may exert in maintaining the population of France has not as yet been fully determined, but it is clear that Dr. Drouineau suspects that this immigration may be a by no means unimportant factor in maintaining the balances still existing. An examination of the figures for the decennial period 1889–1898 leads much to the same conclusions as those for 1898 alone, and a map which accompanies Dr. Drouineau's paper illustrates graphically the departments in which this decay of population has set in, and shows also that in Brittany something of the pristine vigour still obtains. Farthermore when the statistics of the years 1879–1888 are compared with those for 1889–1898 the same story of diminishing increase has to be told, and in the truly eloquent words of Dr. Drouineau: "De période en période cet excédent diminue, les départements à excédent mortuaire augmentent, ce sombre voile de deuil et de ruine s'étend sur le territoire, en même temps qu'il devient plus opaque, plus épais." Are the people of France, he asks, to regard the situation as normal? Has the disease been discovered without the remedy? Or is it necessary to await the experience of yet another decade before the forces at work are inquired into and the causes, if possible, remedied? The French are reminded that the State quite recently voted large sums to place France in a position to resist plague, and the question is asked whether this slow and progressive ruin is less worthy of attention than plague or cholera. This question of the fecundity of races is touched upon by a Dutch writer in the February number of the *Revue des Deux Mondes*. Referring to the remarkable fecundity of the Boer women he urges that even if the arms of England are eventually victorious and the South African Republics come beneath the English flag, the future belongs to the Boer. In less than a century, he tells his readers, the Boers, thanks to their marvellous fecundity, have increased from 60,000 to half a million. In the century which now dawns they will increase, he says in his peroration, to three, four, or five millions, and South Africa will be theirs.

[1] 19 Q. B. D. 582.

SUBDURAL HÆMORRHAGE FOLLOWED BY LOSS OF ABILITY TO NAME OBJECTS.

DR. GRAEME M. HAMMOND of New York records[1] the following interesting case bearing on the presence of a centre in the cerebral cortex where auditory memories of words are stored. A young man, aged 25 years, clerk, free from syphilis and of temperate habits, had suffered for some months from albuminuria with granular casts. During a street fight he was struck on the left temple with a loaded whip-handle. He was knocked down but did not lose consciousness and was able to get up and to walk home, though a few days later he was seized with an attack of general convulsions of a severe and prolonged character. When he regained consciousness it was observed that he had completely lost the ability to name objects and persons. There were no disorders of smell, taste, vision, or hearing during clinical examination. There was no motor paralysis or derangement of sensibility. There was neither word-blindness nor incapacity for uttering words. "He could talk and voluntarily say all words except the names of objects and persons. He could say his own name easily and did so whenever asked to. He readily recognised all objects he saw and indicated by appropriate gestures that he understood what they were and what they were used for, but he could not say the name of a single one even when he was told what the name was." When told to describe how he got hurt he said: "I was struck on the—yes, sir—here, sir (pointing to his head), by (after an attempt to remember the name of the person who struck him) an acquaintance. He hit me with a—(here a pantomime illustrating the size of the implement which he was struck with)." When told to write such words as "cat" and "horse," he wrote "crat" and "heort." He also made errors when told to say or write the alphabet. Ophthalmoscopic examination showed the disc to be slightly choked in the right eye. The diagnosis was subdural hæmorrhage over the posterior part of the left superior temporal convolution. An operation was performed by Dr. Seneca Powell two weeks after the injury. A linear fracture was found in the left temporal bone and a subdural blood-clot was present covering the entire superior temporal gyrus. In the posterior part there was a hole into which a probe could be passed one and a half inches into the gyrus, at the junction of the middle and posterior parts of the convolution. The cerebral tissue was lacerated here, probably by indirect violence, as this point was two and a half inches posterior to the site of the superficial injury produced by the blow. The patient made a good recovery after the operation and at the end of a week began to make successful attempts to pronounce names. "At first the sounds he uttered, while wrong, bore a decided resemblance to the word he desired to say. Later he acquired greater accuracy and now is able to recall the memory of the names of many objects and people." Dr. Hammond concludes by observing that while the conception of a word often depends upon the simultaneous combination of several perceptions any interference with one or more of these perceptions may prevent the conception of a name. Nevertheless there must be a distinct centre in the cerebral hemisphere which retains name memories. This centre forms the nucleus, as it were, of the larger auditory centre. Its topographical position probably varies in different brains.

SLEEPING OUT OF DOORS FOR PHTHISICAL PATIENTS.

IN a paper read before the Medical and Chirurgical Faculty of Maryland and published in the January number of the *Maryland Medical Journal* Dr. O. S. Millet of Brockton, Massachusetts, describes the effects of sleeping out of doors as observed in five cases of phthisis. At the outset he remarks that the New England climate has a national reputation for insalubrity, variability, and bleak east winds, and it was with patients living in this region within a few miles of the ocean on a flat, low-lying country that he had to deal. Nearly two years ago he was called to see a young man who was suffering from cough, wheezing, and dyspnœa, and had a temperature of 100·5° F. Throughout that winter he became worse until in the spring he had lost nearly 15 lb. and was so weak that he could not bring in a hod of coal without extreme shortness of breath. In May, 1898, incipient phthisis was diagnosed; the family history was also extremely phthisical. Dr. Millet then urged him to try sleeping out of doors. He began on the last day of June, 1898, and slept with no awning or roof over his head for five consecutive months, with the exception of only nine nights when rainy weather prevented. Within the first two weeks it could be seen that he was making progress in the right direction. At the end of a month his temperature was normal and his cough and wheezing had almost disappeared. In November, 1898, he weighed 144 lb., having gained 22 lb. in four months. The only medicine which he took was tincture of nux vomica. He has continued perfectly well ever since and now weighs 147 lb. His sleeping-place had a south-west exposure. A photograph of it shows that it was a platform supported by brackets and posts outside the first-floor windows of a small house and sheltered on two sides, being in the corner formed by a projecting part of the building. The man worked in a shoe factory nine hours a day without the loss of a day since his treatment began. While sleeping out of doors he wore a soft felt hat and cotton nightshirt and was covered with the ordinary bed clothes. He usually went to bed early, at 9 P.M., because the sun awakened him early in the morning. Four other photographs show similar sleeping places used by four other patients. One was a man, aged 64 years, who had slept upon the platform since July and had gained 11 lb. Another was a boy, aged 12 years, in whom the amount of lung tissue involved was too extensive to justify the expectation of permanent arrest, but he gained 19½ lb. during the summer. His mother slept at night on another cot beside him, and herself gained very decidedly in weight, strength, and colour. Another patient gained 10 lb. and the physical signs nearly all disappeared. As a matter of experiment Dr. Millet himself has slept and at the date of his paper (Nov. 18th, 1899) was sleeping on a roof garden, and he says, "Until you have tried it yourself you cannot know how much more refreshed one feels after a night's rest out of doors." No particular kinds of bed clothing were used provided that the sleepers were warm, and during the cooler months some of them, therefore, found it necessary to use woollen night gowns and sheets. Many times they found their bed coverings and night-clothes wet with dew, and once in a while a summer's rain disturbed their slumbers but with no harm beyond the necessity of drying the coverings before next bedtime.

---

[1] Journal of Nervous and Mental Disease, December, 1899.

A CASE OF ENTERIC FEVER IN A TUBERCULOUS SUBJECT: NEGATIVE SERO-DIAGNOSIS.

THE case of which the following is an abridgment will be found reported *in extenso* in the *Archives de Médecine et de Pharmacie Militaires* for January, 1900, by Dr. E. J. Debrie, Médecin Major de 1re Classe. An infantry soldier, whose military medical history included chorea, bronchitis, and on two occasions hæmoptysis, was admitted to hospital on Jan. 19th, 1899, on account of nocturnal incontinence of urine, an affection from which he was said to have suffered during boyhood. On admission a note was entered to the effect that the patient was emaciated and of poor physique, with abbreviation of the respiratory murmur in the apex of the right lung, while on the left side the cardiac sounds were unduly prolonged upwards. In order that the patient might be awakened every second hour he was placed in a bed adjoining that of an enteric fever patient, an artilleryman, whose condition was thought grave enough to necessitate constant watching. On March 3rd the gunner died and on the 13th of the same month the other patient began to show signs of gastro-enteric disturbance, his evening temperature being 102.2° F. He was immediately placed on low diet and ordered 30 grammes of sulphate of magnesia. On March 14th his evening temperature was still 102.2° and there were signs of pulmonary congestion, especially on the right side, but with regard to his heart and abdomen the symptoms were negative. Henceforward the notes ran as follows. March 19th.—Since the last report two grammes of antipyrin have been administered daily, but in spite of this the temperature is unchanged. The abdomen is now found to be slightly tense and gurgling can readily be made out in the right iliac fossa. He coughs frequently, and on auscultation moist râles are to be heard in the lower lobes of both lungs. The heart sounds are normal. March 23rd.—The temperature has risen to 104°, the abdomen is greatly swollen, and a profuse eruption of rose-coloured spots has made its appearance. These signs, together with the dry tongue and pulmonary congestion, seem to point to typhoid fever, but owing to the absence of diarrhœa and stupor and also to the fact that an epidemic of influenza is prevalent the diagnosis cannot be definitely settled. The cold bath system of treatment is nevertheless deemed expedient pending a report from the laboratory at Lyons where a specimen of the patient's blood has been sent for examination. March 26th.—*The sero-diagnostic test gave negative results.* In spite of the cold bathing, which has been strictly carried out, the patient's temperature has scarcely varied, remaining constantly at about 104°. The typhoid fever signs have also become accentuated, diarrhœa and stupor have both set in, and the pulmonary congestion now manifests itself by sibilant râles over both lungs. April 2nd.—Owing to the severity of the pulmonary complication, and in view of the negative report from Lyons, the cold baths were stopped. The patient is to be given four grammes of antipyrin daily instead of two. April 3rd.—At the patient's earnest request the administration of the cold baths is resumed. The symptoms of typhoid fever have become plainer. A fresh crop of rose-coloured spots has appeared, the abdomen is more tense than at first, the spleen is enlarged, and the diarrhœa has become profuse. Specimens of blood and sputum were sent to Lyons. April 5th.—The general condition has changed greatly for the worse, the emaciation being extreme, while in spite of everything that can be done the temperature remains at or about 104°. At night the patient is delirious and in the daytime he trembles continually. The pulse is 130, but the heart sounds are well defined. April 7th.—The patient died at about half an hour from midnight, the symptoms towards the end being those of asphyxia, with delirium and nervous excitement. Two days afterwards the second report from Lyons (sent on April 3rd) was received. It was to the following effect: "The bacilli of Koch were present in very large numbers in the sputum. *Sero-reaction negative.*" A necropsy was performed 30 hours after death, when numerous ulcerations absolutely characteristic of typhoid fever were found in the ileum. The large intestine likewise contained ulcers, but here the exact nature of the lesions was doubtful. Dysentery could at once be eliminated, but the writer is unable to say positively whether he had to do with typhoid ulcerations or with a tuberculous condition. In order to decide the point he wished to invoke the aid of the microscope and to that end portions of intestine were sent to the laboratory for investigation. Unfortunately, however, putrefaction had set in and no reliable conclusions could be drawn. In the case of the artillery soldier beside whose bed the unfortunate patient was placed the nature of the disease (which at first was unrecognised) was announced by the serum test while the patient was *in extremis*, and the diagnosis was fully confirmed by the post-mortem examination.

THE PUBLIC HEALTH OF NANTWICH.

THE small country town of Nantwich is fortunate enough to number among her sons Mr. Baldwin Latham, the well-known sanitary engineer, and as occasion has arisen he has always very good-naturedly placed his services at the disposal of the governing body of the town. Most towns of the size of Nantwich—its population is under 8000—would think themselves extremely fortunate to be able to command the gratuitous services of so eminent an adviser as Mr. Latham. The Nantwich District Council evidently think that he is to be congratulated upon being permitted to advise such an authority, for when his report was recently read upon schemes to provide for the proper disposal of the sewage of the town involving an outlay in one case of £10,000 and in the other of £15,000 it was treated with but scant courtesy, and when one member suggested that the report should at any rate be printed in order that its details might be thoroughly understood, another councillor objected because it would involve "considerable cost" and proposed that "abstracts only" should be printed. Eventually it was decided to hold a special meeting of the council to consider the report and the clerk was instructed to obtain estimates for printing 100 copies of the report. In the event of the council deciding to incur the "considerable cost" involved it would not be amiss to add as an appendix to the document a few statements culled from the last annual report of the medical officer of health of Cheshire, such as: "The river Weaver is still seriously polluted by the sewage of the town of Nantwich," "the death-rate at Nantwich in 1898 from all causes was 20 per 1000 and from zymotic diseases 2·2 per 1000, the mean death-rates for the previous six years being 19 6 and 2 4 respectively." The dissemination of such facts would absolve the Nantwich District Council from the charge of any extravagance in the matter of printing.

THE CHAIR OF PRACTICE OF PHYSIC IN THE UNIVERSITY OF EDINBURGH.

THE lamented death of Sir T. Grainger Stewart creates a vacancy in the Professorship of Practice of Physic and Clinical Medicine in the University of Edinburgh. It need not be said that this professorship is one of the most coveted academical positions in Great Britain; it confers good opportunities for teaching, the emolument is good, and it generally carries with it in Scotland great advantage and distinction in consulting practice. To fill the chair of Medicine at Edinburgh can never be other than an object of honourable rivalry with the best teachers. It would be premature at present to indicate any sense of preference for the candidates from whom the curators will have the great responsibility of choosing. Among the gentlemen spoken of as likely to be candidates are Dr. Byrom Bramwell, Dr. John Wyllie, Dr. George Alexander Gibson, Dr. Alexander James, and Dr. Robert Alexander Fleming. We believe also that Professor Osler would come from Baltimore if the chair were offered to him. His appointment would no doubt be an excellent one, for the erudition, eloquence, and practical knowledge of the learned Canadian, who is a Fellow of the Royal Society and the Royal College of Physicians of London and a Professor in an American University, are known to all.

AN UNUSUAL CASE OF LEAD-PARALYSIS.

DR. B. ONUF reported a case of the above at the New York Neurological Society on Jan. 2nd which has features of special interest. The case is that of a man, aged 37 years, and by occupation a painter. He had had one attack of lead colic some years ago. Both family and personal history were good. A short time ago he had a severe fall and for several days after this he appeared to be dazed and confused From March till August, 1899, he suffered severely from colic and had done no painting; then he had resumed his occupation and was at work with paints containing a large proportion of lead. At the end of August he had become quite ill and unfit for work and in three or four days he developed paraplegia and was put into bed in a helpless condition. His left arm also showed a considerable diminution of power. He was then removed to St. Catherine's Hospital in September. On admission to hospital there was found a complete flaccid paralysis of both the lower extremities. The knee-jerks were absent and there was marked tenderness of the nerve-trunks and muscles of the legs A paralysis of the flexor muscles of the left arm and of the extensors of the fingers was also noticed and a "blue line" was present in the gums. He was put under treatment and diaphoretic remedies were administered. The pain and tenderness in the limbs diminished, but a more serious symptom—viz., dyspnœa—now supervened. On Oct. 4th he had a severe attack of dyspnœa and on the following morning he had another and similar attack in the course of which he died. The necropsy revealed the following interesting conditions. The flexors and extensors of the right arm were found to be atrophied and wasted, as were also the peroneal muscles and the flexors of the thigh. The left lung was the seat of broncho-pneumonia. The spinal cord showed poliomyelitis of the anterior cornua. At the second and fifth lumbar segments there was an intense degree of infiltration of the walls of the blood-vessels with small round cells. The infiltration had been so extensive as partially to destroy and quite alter the appearance of the nerve-cells in the grey substance. The anterior spinal roots were markedly involved and showed evidences of degeneration, but the *posterior lumbar roots* appeared to be normal. The plantar nerve showed an increase of connective tissue and its vessels gave evidence of endarteritis obliterans. The liver was set aside and was subsequently examined by Dr. J. Bookman for lead, but none could be found. Dr. Onuf points out that as five weeks had elapsed since the patient had left off using paints the absence of lead in the liver was not to be wondered at.

THE COMMITTEES OF THE GENERAL MEDICAL COUNCIL.

VARIOUS committees of the General Medical Council have been summoned for next week. The Executive Committee is summoned for Monday, Feb. 26th; the Penal Cases Committee for Tuesday, the 27th; and the Medical Aid Associations Committee for Wednesday, the 28th. The Executive Committee will not be complete; Mr. Brudenell Carter being no longer a member of the Council, his place will be vacant. Clause 5 of Standing Order VII. runs as follows:—

> "Should there occur during the recess any vacancy in the Executive Committee, they [the committee] shall be empowered to fill up such vacancy except in cases where a summons has been issued for a meeting of the General Council, when the Council itself shall elect."

It remains to be seen whether the Executive Committee will think it necessary under this by-law to anticipate the annual election of their body, which takes place in May. The terms of the clause seem to contemplate such action, and it is the more necessary as there will be another meeting of the Executive Committee before the meeting of the General Medical Council.

THE TREATMENT OF EPILEPSY BY BROMIDES AND DIMINUTION IN THE INGESTION OF CHLORIDES.

DR. Ch. Richet and Dr. Ed. Toulouse have recently brought before the Académie des Sciences in Paris a very ingenious modification of the bromide treatment of epilepsy which has given good results. At the meeting of the Société Médicale des Hôpitaux on Jan. 12th Dr. Toulouse returned to the subject. The idea occurred to him that privation of chlorides would produce increased attraction of the cells for similar salts—bromides—and would therefore intensify their action. The results justified the hypothesis. About 14 grammes (210 grains) of chloride of sodium are consumed daily by normal persons under normal conditions, but this quantity is not necessary to the economy, and according to some observers it is even injurious as the kidneys are overworked in its elimination. Dr. Toulouse reduced the quantity of chloride of sodium consumed by his patients to two grammes (30 grains) a day by putting them on the following diet: milk, 1000 grammes (35 ounces);

beef, 300 grammes (10 ounces); potatoes, 300 grammes (10 ounces); flour, 200 grammes (seven ounces); sugar, 50 grammes (one and three quarter ounces); coffee, 10 grammes (154 grains); and butter, 40 grammes (one and a half ounces nearly). The food was given in the following form. At 7 A.M., nine ounces of milk; at 11 A.M., two pancakes made with eggs, flour, milk, and sugar, and coffee; at 3 P.M., pap made with flour and sugar diluted with milk; at 5 P.M., broth, boiled beef, and potatoes roasted with butter—all without salt. The remainder of the milk was drunk with water. The patients were inmates of an asylum and the subjects of frequent epileptic fits. Bromide of sodium in daily doses of about 50 grains was given to nine patients. On ordinary diet an average of 9·54 fits occurred in 10 days, but in the patients on the diet described the average fell to 1·10—a diminution of 87 per cent. The value of the treatment was confirmed by the fact that the attacks returned when ordinary diet was resumed although the bromide treatment was continued. Whether the prolonged use of this method produces any permanent effect on the disease was not determined. The regimen alone could not explain the effect, for when bromide was not given it produced no benefit. Dr. Toulouse thinks that possibly good results may be obtained in a simpler manner—by removing salt from the ordinary diet and taking into account the quantity contained in bread. This principle of modifying the nutrition of the organism so as to render it more susceptible to the action of a remedy, which Dr. Toulouse terms "*thérapeutique métatrophique*," presents a wide field of application and possibly of utility. For example, the action of iodides in syphilis might be increased by diminution of the chlorides in the system. It also presents a wide field for errors.

PRODROMAL RASHES IN MEASLES.

THE question of prodromal rashes in measles does not appear to be ever entertained in English works. An important article entitled "Sur quelques Erythèmes Prémorbilleux" has been published in *La France Médicale* of Dec. 22nd, 1899, by Dr. E. Deschamps. Professor Henoch appears to have first drawn attention to the subject. He states that "the skin in the prodromal stage usually shows no morbid phenomena; very small rose papules and exceptionally a fugitive erythema are rarely observed on the face." He relates the case of a child, aged two years, in which cough and pyrexia suddenly appeared with diffuse redness of the face and chest. On the next day the redness had disappeared and there were broncho-pneumonia and severe diarrhœa. In the night of the third day the eruption of measles appeared. Some years later Talamon published the case of a boy, aged 10 years, in which during the period of invasion urticarial erythema supervened.[1] In the following year Surmont saw a child, aged three and a half years, with an urticarial eruption which preceded by one and a half days the eruption of measles.[2] But the first systematic work on the subject is the thesis of Dr. G. Robet published in 1896. He observed six cases at the Hôpital des Enfants Malades, Paris. Out of the 10 cases to which he refers, in three the rash was scarlatiniform, in three urticarial, in one morbilliform, and in two it was red *miliaria*. Dr. Deschamps relates seven cases of which some were personal observations and others were reported to him. The following is an example of the former. A boy, aged 12 years, had a bad sore-throat; the pharynx and tonsils (which were very large) were red and ecchymotic. The face, hands, and wrists were very red and there was a scarlatiniform rash on the forearms and legs. The temperature was 98.3° F. in the morning and 101·5° in the evening. On the following day the fever had disappeared. The throat became paler and the rash disappeared in 48 hours. But the fever re-appeared on the third day when there was also diarrhœa. On the fourth day the child complained of his throat and sneezed and his eyes became red, and in the evening the eruption of measles appeared. The prodromal rash of measles usually appears four or five days before the true eruption—at the onset of the period of invasion. Prodromal rashes occur especially in measles and in rubella, more rarely in diphtheria, pneumonia, scarlet fever, varicella, and whooping-cough. The rash is a fugitive erythema; in some cases it lasts from 24 to 36 hours, rarely more than three days. In many cases it is scarlatiniform and in others it resembles measles, but the face is exempt and there is no conjunctivitis. The temperature is generally not affected by the rash, but the child is generally apathetic and without appetite. As to the pathology, Dr. Deschamps argues that it is due to streptococcic or other infection. For in a number of cases sore throat, digestive troubles and diarrhœa have been observed, and in the mucous secretions in measles streptococci and pneumococci have been found. Probably the infection of measles increases the virulence of the associated microbes. The prognosis does not appear to be affected by these prodromal rashes. On the contrary, certain cases observed by M. Hutinel in which erythemata supervened during the eruptive or convalescent periods of measles were usually fatal.[3]

GRANTS IN AID OF SCIENTIFIC RESEARCH IN DENTISTRY.

THE Odontological Society of Great Britain is to be heartily congratulated upon the step it has recently taken in instituting grants in aid of scientific research in connexion with dentistry. In recent years the value of scientific research in dentistry has steadily gained ground and there is little doubt that in the future progress will depend more upon the results of patient experimental research than upon mere clinical observation. In dentistry many fields for research are open to the investigator and there is ample room, not only for the histologist and pathologist, but also for the chemist and metallurgist. The society has sent us a list of the regulations in connexion with these grants. Briefly they are as follows: (1) the grants will be only given in aid of work in connexion with dentistry; (2) where the grants cover the whole expense of inquiry the result of the investigations becomes the property of the Odontological Society; and (3) that all apparatus purchased with the grant shall be the property of the society. The Council is open to receive applications for grants and full particulars can be obtained from the honorary secretary of the society at 40, Leicester-square, W.C.

THE LATE SIR W. D. GEDDES, PRINCIPAL OF ABERDEEN UNIVERSITY.

DISTINGUISHED as a classical scholar and not less as an academic administrator, Sir W. D. Geddes, by his sudden death, leaves Aberdeen, and the whole cause of professional education, "a man the poorer." In the literary sphere he will long be remembered for his prelections, academic and popular, for his masterly commentary on the "Phædo" of Plato, for his profoundly suggestive contributions to the Homeric controversy, and for his edition, in two volumes quarto, of the Latin poems of Arthur Johnston, physician to King Charles I., and known to the Europe of the seventeenth and eighteenth centuries as the "Medical Ovid." It is his work, however, in university extension that more particularly interests the profession—work begun in 1885 when he became principal of Aberdeen University—work, moreover, carried on in spite of difficulties often seemingly insuperable, till almost within sight of the goal. By his untimely death he bequeaths to others the consummation he had most at heart—to make the northern school complete in every department of academic, especially medical, culture and qualification. Even as it is the teaching of medicine is under deep obligations to his enlightened recognition of its requirements, preliminary, scientific, and clinical, and Aberdeen will owe it largely to him if she reinforces the profession with scholars and consultants equal in the coming generation to the Adamses and Kilgours of the past.

THE CONGRESS OF INTERNAL MEDICINE.

THE eighteenth Congress of Internal Medicine will be held at Wiesbaden from April 18th to 21st under the presidency of Professor von Jaksch of Prague. On the opening day a discussion on the Treatment of Pneumonia will be introduced by Dr. von Korányi of Budapest and Dr. Pel of Amsterdam. On April 20th Dr. Litten of Berlin will introduce a discussion on Endocarditis and its Relations to other Diseases. The titles of several papers to be read are already announced. Any medical man may become a member. The price of a member's ticket is 15 marks, which entitles the holder to receive a copy of the Transactions. In connexion with the Congress there will be an exhibition of recent medical appliances. The permanent secretary is Dr. Emil Pfeiffer, 13, Parkstrasse, Wiesbaden.

PARALYSIS OF THE FACIAL AND HYPOGLOSSAL NERVES.

Two recent and interesting contributions referring to the above forms of paralysis have been published by Oppenheim[1] and Hoffmann.[2] In the case recorded by Oppenheim the patient was during early childhood the subject of fits which produced unconsciousness lasting several days, and on recovering consciousness there developed a paralysis of the face on the left side and a paralysis of the corresponding side of the tongue. The paralysis was partially recovered from afterwards, though some local atrophy of the affected muscles remained as a persistent condition. The patient came again under observation 18 years later when the muscular paralysis and atrophy mentioned above were still present. Fibrillary tremors were also met with and the electrical excitability of the left facial region was quantitatively diminished. The knee-jerk on the right side was exaggerated, and from a consideration of the clinical facts and history of the case it was believed to be an instance of encephalitis of the pons—a disease which has received but little attention, although there can be no doubt that such an affection, comparable to the spinal and bulbar forms of infantile paralysis, does exist. Of the facial muscles affected in the first instance, some—e.g., the orbicularis palpebrarum and orbicularis oris—had recovered their power. The platysma myoides showed a paralysis of its lateral portion, while the fibres of the median portion still seemed active. From the fact that muscles near the median line—viz , the mentalis, quadratus menti, orbicularis oris, and corrugator supercilii—were readily stimulated by, and responded to, the electric current applied to the sound side, Oppenheim draws the practical conclusion that these muscles were innervated from the facial nerve of the opposite side. The case related by Hoffmann is that of a girl, 17 years of age, who during childhood had suffered from chronic otitis media. This was subsequently followed by cellulitis of the neck, itself probably the sequel to a sore-throat. The local lymphatic glands in the side of the neck were inflamed and swollen and it is probable that the inflammatory process spread into and involved the trunk of the hypoglossal nerve. There were no bulbar or spinal symptoms, and this fact, coupled with the absence of general pain and of fever, negatived the idea of poliomyelitis or of an acute condition such as hæmorrhage. The patient did not perceive anything wrong with her tongue for a considerable time and meanwhile hemiatrophy of the tongue had made some progress. Fibrillary tremors were present during examination on both sides of the tongue and the application of the electric current to the neck was efficient in provoking appropriate movements of deglutition in which the muscles on both sides of the pharynx participated. Hoffman also points out that in the process of protrusion of the tongue the paralysed half lagged behind and thus caused a curvature of the body of the tongue with the concavity towards the paralysed side, while in retraction of the tongue from the condition of extreme protrusion these appearances were reversed. He is of opinion that in this case the hypoglossal nerve was not entirely affected, but that some of its fibres must have escaped destruction. The two cases mentioned above illustrate two different kinds of lesion which may affect a peripheral organ like the tongue, and produce somewhat similar clinical symptoms, though the cases were very different in causation and in gravity of prognosis.

THE GOVERNMENT AND THE REPORT OF THE ROYAL COMMISSION ON THE LICENSING LAWS.

THE Government gave, through the Home Secretary, the following answer to a question asked by Sir J. Leng as to the intentions of the Government with regard to this report: "Of course, I have given my best consideration to the report of this Commission, but I am *obliged* to say that in view of the difficulties of the question and in the present circumstances the Government do not see their way to make any promises of legislation during the present session." It must be allowed that "in the present circumstances" the Government may well ask to be excused from considering this important report. But they will make a great mistake if they think that anything in the difficult nature of the subject will free *them from* the responsibility of dealing with it and *that* soon. The vice of drinking is more costly to the nation even than war.

"THE DIAGNOSIS AND TREATMENT OF HEPATIC ABSCESS."

DR. H. MALBOT, a retired surgeon-major of the French army who gained his experience in Algeria where he saw 22 cases of hepatic suppuration, has recently concluded a series of articles on the above subject in a Parisian medical journal.[1] According to this observer we should see many more cases of abscess of the liver recorded if the diagnosis of the affection were less difficult and its semeiology less uncertain. Pain he regards as the most important of the symptoms. It presents itself in two chief forms: 1. A feeling as though some structure were being torn, resembling in some respects an electric shock, situated in the hepatic region and always occurring after a sudden movement or an attempted muscular effort. 2. Pain *brought on* by succussion lancinating or pungent, extending towards the right shoulder, the pit of the stomach, the lower part of the abdomen, or the right iliac fossa, according to the situation of the abscess. This painful succussion according to Dr. Malbot, is well-nigh pathognomonic of hepatic suppuration. Externally an abscess manifests itself by the "coving" and deformity of the gland rather than by its hypertrophy. As for the attendant *fever*,

[1] Archives Générales de Médecine, August, September, and October, 1899.

It has no special characteristics and may assume any type. Sometimes even it is altogether absent. Dr. Malbot has never observed the peritoneal friction mentioned by certain writers and he also ignores their pulsation of the liver. Neither has he ever met with a case that was complicated by jaundice. After all, he says, the only absolutely certain indication of hepatic abscess is the presence of pus, as shown by an exploratory puncture. These punctures are quite harmless and if unsuccessful at the first attempt should be repeated several times in different directions. With regard to the pathology of hepatic suppuration Dr. Malbot differs from Kelsch, Kiener, and the other authorities who seek to incriminate dysentery as the sole source of the disorder. In his opinion abscess of the liver, as seen at all events in Algeria, may owe its origin to a multiplicity of causes. Any factor which tends to lower the tone of the system and impair its powers of resistance, such as heat, damp, improper food, malaria, and intestinal ulceration of any kind (even typhoid and tuberculous), may lead to hepatic suppuration. In treating abscess of the liver prompt surgical intervention is essential. As soon as possible the accumulation of pus should be removed by means of a free incision. Adhesions being rare Dr. Malbot directs an assistant to immobilise and at the same time compress the organ with both hands before he himself uses the knife. When the pus has been evacuated the cavity is washed out preparatory to the insertion of four, five, or six large red rubber drainage-tubes which are so arranged that the wound is completely plugged, thus rendering the escape of pus into the peritoneal sac an impossibility. This procedure Dr. Malbot calls "nailing the liver to the parietes." Its success at his hands has been considerable, the average duration before perfect cicatrisation of seven cases having been 14 days.

THE CEYLON BACTERIOLOGICAL INSTITUTE.

It is a well-known fact, and one upon which the British nation has received somewhat carping criticism from many foreigners, that scientific research in the British Empire receives scarcely any aid at the hands of the State. But the converse view shows a prospect of which we may well be proud, and that is the generosity and readiness of British subjects to forward with their best endeavours efforts for the advancement of science In London we have the great hospitals, and the laboratories of the Royal Institution built and endowed by Mond. In India the great feudatory princes and munificent commoners among the Parsees have given freely of their wealth for the founding of research laboratories and other scientific work; and now from the island of Ceylon comes the news that a bacteriological institute has been given by the generosity of a well-known family in the island—namely, the de Soysas. Some eight years ago Mr. J. W. Charles de Soysa offered the Government a sum of 10,000 rupees for the erection of a Pasteur institute, but the authorities did not see their way to accept the gift. In 1897, however, Mr. de Soysa renewed his offer for the purpose of building a bacteriological institute and, further, when it was found that the proposed building would cost far more than the sum originally offered he undertook to find funds for the erection of a building on a plan approved by the Government. In this work he was ably assisted by Dr. Marcus Fernando, who spared no time or trouble in arranging the details of the building and in personally superintending its construction after the best European models. On Jan. 31st the institute was formally opened by the Governor, when Mr. A. Perry, principal colonial medical officer, read a statement concerning the founding of the institute. His Excellency then declared the buildings open, with a few words of warm thanks to Mr. de Soysa for his munificence. The director of the institute will be Dr. Marcus Fernando. The building is equipped with the latest appliances for bacteriological research and a number of specimens were on view at the time of opening. A marble slab on the main wall bears the following inscription: "The de Soysa Bacteriological Institute. Presented to the Government of Ceylon by J. W. Chas. de Soysa, Esq., J.P., in commemoration of the Diamond Jubilee of Her Most Gracious Majesty the Queen. Opened by H.E. Sir Joseph West Ridgeway, K.C.B., K.C.S.I., Governor, January 31st, 1900."

The following resolution was unanimously passed at a meeting of the Bradford and West Riding Medical Union held on Feb. 15th:—"The members of the Bradford and West Riding Medical Union beg to offer their hearty congratulations to Professor Victor Horsley, F.R.S., one of the Direct Representatives of the medical profession on the General Medical Council, on the success with which he has struggled to defend the interests of medical practitioners against the continual neglect shown by the representatives of corporations on the General Medical Council, and hope that the medical profession may long continue to have the advantage of being represented on the Council by a gentleman so distinguished alike by scientific attainments and by remarkable energy and skill in pushing the work of reform which is so much needed."

At the monthly board meeting of St. John's Hospital for Diseases of the Skin on Feb. 13th the Earl of Chesterfield was presented with a silver inkstand by the medical staff and governors of the institution as a mark of their esteem on the occasion of his marriage. Mr. G. A. Berkeley, the treasurer, thanked Lord Chesterfield for the time which he had devoted to the hospital and the tact with which he had steered it on several critical occasions into its present smooth and peaceable waters.

Mr. A. H. Spurrier, medical superintendent of the Government Leper Asylum at Zanzibar, reports that he has found in three places on the outskirts of Zanzibar city the breeding places of the true fever-bearing mosquito. From them he has succeeded in hatching the anopheles. We learn that he has also found a larva which preys upon the mosquito larva to a formidable extent—a discovery which may have considerable significance.

On Feb. 16th the Queen, who was accompanied by Princess Henry of Battenberg and Princess Victoria of Schleswig-Holstein, the Duchess of Roxburghe, Mrs. Mallet, Miss Minnie Cochrane, and Sir John MacNeill being in attendance, visited the Royal Isle of Wight Infirmary. She was received by the Rev. W. Welby and Dr. A. G. Davey and was wheeled in a chair to the Children's Wing, which she had opened last year in commemoration of her Diamond Jubilee.

We are forced to delay dealing with the report published this week by the London County Council on the bacterial treatment of crude sewage. The report, which is a supplementary one, is of considerable interest, for in it Dr. Clowes and Dr. Houston give some particulars of the physical, chemical, and bacteriological character of the deposit which accumulates on the coke beds at Barking and Crossness.

At the meeting of the Medical Society of London on Monday next the discussion on the Pathology and Treatment of Appendicitis will be resumed. The following points are suggested for discussion: (1) non-operative treatment; (2) indications for operative treatment; (3) nature of operation and any special details; and (4) after-treatment.

Dr. Dudley Buxton will open the adjourned discussion on the After-effects of Ether Inhalation at the next meeting

THE WAR IN SOUTH AFRICA.

SINCE we last wrote the complexion of affairs in South Africa has altered for the better. Our forces have now been concentrated and they are engaged in a course of action which has so far proved successful. Kimberley has been relieved by a brilliant march; the Boer strongholds at Magersfontein and Spytfontein have been evacuated and occupied by British troops, and the main body of General Cronje's army are fighting a rearguard action while endeavouring to escape towards Bloemfontein, the result of which is not known yet. There is active and energetic movement on all sides; the noise of battle is heard in the western, the eastern, and the southern regions of the conflict, and news of grave import and of a decisive nature may arrive at any moment. The Boers never have met, and never will meet if they can help it, British troops in the open. From the time of Sir Harry Smith to the present their tactics have been the same, but on this occasion they may be compelled to change them. General Buller's troops, too, have been active in the direction of Mount Hlangwane and the east of Colenso, pressing the Boers hard and very successfully on the eastern flank of their investing line. If any portion of the forces of the Federal Republics around Ladysmith have been diverted elsewhere for the protection of the Free State, into which Lord Roberts is now actively carrying war, we may confidently hope that the renewed attempt to relieve Ladysmith on the eastern flank will prove successful. The war is by no means over however; there probably remains a good deal of hard and arduous campaigning work and fighting to be yet undertaken, but there can be little doubt that we are on the right track. The pressure put upon the Government to keep on pouring forces into South Africa has done no harm. The nation is prepared to incur any cost and to make any sacrifice to win. To the more thoughtful among us, however, it has been a satisfaction to recognise that Lord Salisbury has kept his equanimity under circumstances where a cool head was eminently needed. He has all along evidently known his own mind, and has maintained the opinion that he did not think that all those embarrassing foreign contingencies which were hinted at "were at hand or likely to be at hand."

The "entanglement" of Ladysmith has hitherto been the great military obstacle to the success of our arms. Sir Redvers Buller has taken upon himself by far the hardest task of the war and it was one which, as he is understood to have foreseen and realised all the difficulties of it, called for some chivalrous courage on his part. He is stated to have been officially opposed to the selection of Ladysmith as a suitable station for the accumulation of military stores on sanitary as well as strategical grounds, and there is no doubt that as regards the former it has an unsatisfactory medical history. Enteric and other forms of fever and dysentery were of frequent occurrence there and its occupation by the present garrison has proved an unfortunate one in these respects. It is reported to have been the depôt of a large collection of stores and valuables and this, we may suppose, together with political reasons, led to its being held. As General Buller probably had no sufficient land transport to undertake at once a march into the Free State, leaving Ladysmith to take care of itself in the meantime, he had no option but to do the best he could and to undertake the relief of Sir George White. However, as he has now taken a position of strategical importance and entrenched his force at Mount Hlangwane and swept the enemy's trenches at Colenso we may expect to hear that he has succeeded in relieving Ladysmith.

It may be interesting to our readers to know that an emergency ration is served out to soldiers to be carried on the person. It consists of one tin of pemmican and one of chocolate. This is only to be used on emergency, of course. The feeding of the British soldier in South Africa is varied and abundant when he can get it.

The special correspondent of the *Standard* of Feb. 16th had some interesting observations regarding the Royal Army Medical Corps in South Africa:—

> Sir William Mac Cormac has just returned from an inspection tour of the various hospitals. It would be difficult to bestow too great praise on the excellent medical arrangements which have been made. No war has ever been fought in which the wounded soldier has been [illegible] with so much care and consideration. Reforms in many directions will have to be introduced into our army, and it is devoutly to be hoped that our system of medical attendance in peace should be again assimilated to that which obtains in war—i.e., that every important unit may have a medical officer attached to it. One thing is quite certain, the Royal Army Medical Corps must be increased in numbers, for it is quite inadequate even for peace, and the practice of suddenly enlarging it by taking men, when war breaks out, who have had no previous connexion with the service is not one to be commended.

We quite think that the corps must be greatly increased. Its officers in South Africa have done admirable service and deserve every consideration. Their opportunities for leave and professional study will have to be enlarged and the pressure of foreign service on them, which is unduly severe, will have to be decreased. We do not see that there is any insurmountable objection to the attachment of a medical officer to a regimental unit as is now done on active service. It could be made to work in with the system of a Royal Army Medical Corps and, but for the expense which it was said to entail, this would have been done many years ago. An additional number of medical officers on the strength of the corps would have the effect of giving more leave to the remainder. Moreover, the number of medical reserve officers in the country might be increased to meet the exigencies of war when it occurred and in order to enable them to obtain some army training and knowledge of military methods of procedure during times of peace so as to fit them for their work when they were called upon to act in time of war. But there will soon come a time when a complete change must take place in our whole army system, and the change will take the shape of a welding together of the different and various forces of which it is composed.

The present war has not only taught this country, but every other country, a good deal, and has been fruitful of suggestion in many ways. It has given an impetus to the physical training of the youth and young manhood of this country with enormous advantage to manliness and health, physical and moral alike. It has shown the possibility of immensely increasing the strength of defensive warfare. We agree with Lord George Hamilton in thinking that the successful invasion of a country would become a most difficult, if not impossible, undertaking if the adult male population were able to use with intelligence the rifles and modern weapons of warfare, and had undergone some elementary military training, which would also have an excellent influence in the way of personal hygiene. The war has taught us, too, the use, hitherto unsuspected, that might be made of the mountain frontier of India against a hostile and invading army. We have all read of the courage, discipline, and physical attributes of our officers and soldiers in South Africa with admiration. We have yet to prove how far these attributes are capable of being brought out and cultivated by physical training in the open air, and by the development of a similar spirit of obedience and self-reliance among other people than soldiers.

THE PRINCESS CHRISTIAN HOSPITAL.

The steamship which is to convey this hospital to South Africa for the treatment of our troops will sail from Southampton early next week. It has been presented to the Government by Mr. Alfred Mosely of West Lodge, Hadley Wood, Middlesex, who has entirely equipped it, and will support it and accompany it to the Cape. Mr. Mosely's knowledge of the country and climate, gained during 25 years' connexion with South Africa, will prove of considerable value to the efficient working of the hospital. No trouble or expense has been spared to make the hospital in every way worthy of its work. Major H. B. Mathias, D.S.O., R.A.M.C., who is a brother of the gallant Colonel H. H. Mathias, V.C., of Dargai fame, goes out as Government representative with the hospital. The civil staff will consist of the following:—Chief surgeon: Mr. J. Paul Bush, surgeon to the Bristol Royal Infirmary, lecturer on operative surgery in University College, Bristol, and chief surgeon to the Bristol Constabulary. Medical officers: Dr. G. V. Worthington, late senior house surgeon to St. Bartholomew's Hospital, London; Dr. E. A. Nathan, late house surgeon and house physician to St. Mary's Hospital, London; and Mr. A. L. Flemming, late resident surgical officer to the Bristol Royal Infirmary. Dressers: Mr. A. B. Cridland, house surgeon to the Bristol Eye Hospital and late casualty officer, Bristol Royal Infirmary; and Mr. E. M. Pearse, casualty officer, Bristol Royal Infirmary. Nursing staff:

Sister E. C. [illegible] of Guy's Hospital, who will be the sister in charge, and Sisters M. [illegible] F. Atkins, F. M. Fisher, D. A. Snell, and F. Baker. There will also be six non-commissioned officers and 20 hospital orderlies.

The building will consist of four pavilions, each 120 feet in length and containing 25 beds (100 beds in all), with surgery, operation room, nurses' room, tiled bath rooms, washing room for the men, and lavatories attached. The structure itself will be of corrugated iron, lined inside with greenish tinted canvas. The wards will be comfortably furnished with bedsteads fitted with spring mattresses of the newest design, folding washstands, invalid tables and chairs, and every little detail likely to make them more comfortable and home-like. The surgeries and operation room will be fitted with all the latest improvements, including a very complete Röntgen ray apparatus with all the latest inventions for localising foreign bodies. The accessories include the new mercurial interrupter for making and breaking the current, driven by a special motor of its own. This interrupter gives a particularly steady and distinct image with the fluorescent screen, and it also has the advantage of diminishing the length of time of exposure. An expert in this department is included in the list of medical officers. In addition to the main buildings there will be three stores for warehousing the supplies of provisions, invalid specialities, stimulants, drugs, &c.; there will also be a separate building for the storage of the linen, a laundry, and a very complete kitchen of considerable size. A professed cook and assistants will be in charge of the culinary department. Another large structure will contain a central mess room and sleeping accommodation for the medical officers, nurses, and other members of the staff, which will number in all about 50 persons. The plans and specifications of the hospital were prepared by Mr. [illegible] W. Marks, A.R.I.B.A., and the work has been admirably carried out under his superintendence by Messrs. Humphreys, Limited, of Knightsbridge.

(NOTES FROM SIR WILLIAM MACCORMAC.)

(Continued from p. 4[illegible]3.)

We left Cape Town at 9 P.M. on Jan. 16th by ordinary passenger train and arrived at the small town of Matjesfontein in time for breakfast. This little place is considered to be peculiarly suitable for persons suffering from lung complaints. There is a pleasant looking hotel, with spacious verandahs, situated quite close to the station. This building has been offered by the owner (Mr. Logan) to the military authorities as a hospital and to be maintained at his own expense. Unfortunately it is considered to be too near Cape Town for the purpose and too far away from De Aar (where there is a large stationary hospital) as nothing would be gained by unloading the hospital trains here instead of continuing the journey to Wynberg.

We presently continued our journey, passing through a desolate country. The temperature in the carriage reached 90° F. in the afternoon. The veldt on either side of the railway line, extending as far as the eye can reach (until the view is cut off by volcanic hills rising up from the plain), is almost entirely devoid of cultivation and, indeed, vegetation. It is dotted with clumps of scrub, with here and there a mimosa tree. The innumerable kopjes of arid earth covered by boulders must greatly increase the difficulty of locating one's position in the open by their similarity to each other. The Table Mountain at Cape Town is repeated by similar flat topped hills of smaller size all along the line. We arrived at De Aar Junction about midnight and did not reach Naauwpoort Junction until 5 A.M. on the 18th. I here met Colonel Gubbins, R.A.M.C. (the principal medical officer of this division), and visited General Kelly Kenny at his head quarters, which were situated in a little half finished brick cottage. I visited the field hospital here, under the command of Major Hamilton, R.A.M.C., and also the bearer company, commanded by Major J. Fallon, R.A.M.C. This field hospital is of the usual variety of 100 beds and at present contains but very few sick and wounded and no cases of any peculiar interest. Its managers were hourly expecting orders to proceed to Rensberg. Naauwpoort is now occupied only as a station *en route* for the front, the troops there stationed being only a comparatively few "details." The camp is very healthy.

We left Naauwpoort about 2.30 P.M. for Rensberg for the purpose of visiting General French's command. Lieutenant-Colonel D[illegible], R.A.M.C. (the principal medical officer), met me and we were accommodated with tents which were pitched in the garden of a deserted farmhouse which General French has made into his headquarters. The journey from Naauwpoort occupies two hours, the distance being 20 miles, and soon after our arrival I was asked by the principal medical officer to see a case in the field hospital under Major Tate, R.A.M.C., located here. This was the case of a man whose left femur had been smashed by a bullet through the great trochanter. Secondary hæmorrhage had set in 58 hours after the injury and amputation had been performed at the hip-joint. Copious unhealthy suppuration took place and Lieutenant Porter, R.A.M.C., who was in charge of the case, was just about to make a counter opening for its freer escape and I assisted at this operation. I saw this man again two days later when he was much improved. The septic condition had abated, the temperature was lower, and the suppuration was more healthy. At my last visit to this patient, on Jan. 23rd, his condition, both local and general, was much better and there seemed great hope of his early and complete recovery. Amputations during this campaign have been few in number and there may possibly not be another case of disarticulation at the hip-joint with subsequent recovery. The operation was performed in an ordinary bell tent, which served the purpose as well as can be expected on the field. The dust is a great source of discomfort and trouble in operating and dressing wounds, the soil here being very dry and sandy. The wind is high as a rule and the dust penetrates every cranny. Water is very scarce, the entire supply for the troops having to be brought from Naauwpoort, a formidable item for the transport officers. The flies, which are of the ordinary household variety, are very numerous and it becomes necessary to provide mosquito curtains for all serious cases.

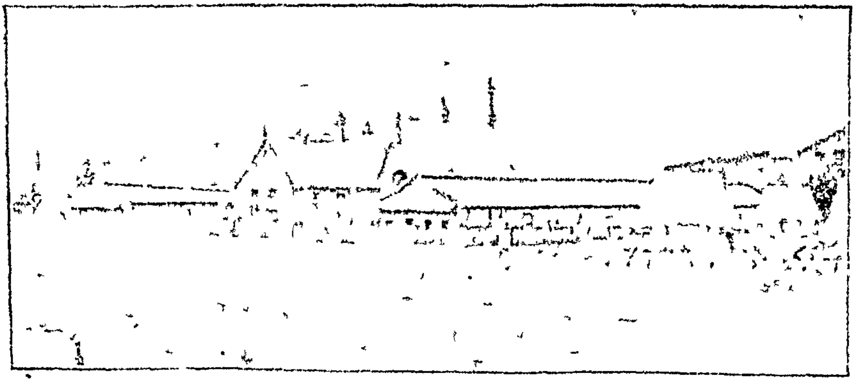
The medical arrangements with this little force are as follows. The troops are practically divided up into two portions, one on each flank, about six or seven miles from Rensberg station. Each regiment has its regimental medical officer constantly with it. Half a field hospital (50 beds) is situated at a farm house at each of these two flank positions and one bearer company is with each half hospital. A complete field hospital (100 beds) is situated here as a fixture, which will be fed by the half hospitals at the front—these latter being, of course, mobile and compelled to evacuate sometimes at an hour's notice. The transport of the wounded and sick is carried on by means of the usual ambulance waggons of the bearer companies. Those cases which are unlikely to recover at the stationary field hospitals are conveyed as they accumulate by train to De Aar Junction, where the large hospital on the line of communication is situated. The hospital trains in an emergency come all the way to Rensberg and thence to a small siding running into the stationary field hospital, but for ordinary cases in times of inactivity at the front a local hospital train of three trucks fitted with stretchers (Zaverdeski's method) is found to be quite sufficient and to answer the purpose admirably, leaving the two regular hospital trains free for the use of the larger force at Modder river.

The following are notes of an interesting case:—

Corporal Thomas (of the Worcester Regiment) Mounted Infantry was wounded at Arundel on Nov. 23rd, 1899, whilst with a party reconnoitring the hills at Arundel. He was leading his pony up a hill when a Boer about 400 yards distant fired at him and hit him four times. All the bullets came from the same rifle; he saw the Boer standing up to fire at him. The first bullet struck the fifth metacarpo-phalangeal joint of the right hand on the extensor surface, smashing the ends of the bones composing the joint, passing along the palmar surface of the metacarpal bones obliquely to its exit between the first and second metacarpal bone and making an irregular oval shaped wound the largest diameter of which was three inches. The exit wound was on the extensor surface of the hand. The irregular ragged appearance of the wound of exit was caused by smashed bones. The second bullet had its entrance in a small, round, punched-out wound, typical of the Mauser bullet, at the base of the palmar surface of the left thumb and passed obliquely upwards and outwards. Its exit was at the extensor surface of the lower extremity of the radius, the exit being irregular. The third bullet entered at the inferior angle of the left scapula, passing directly from behind forwards. (He had turned

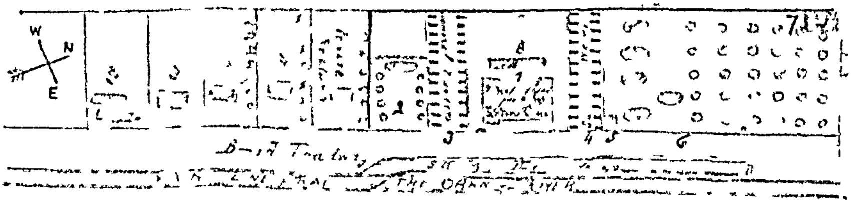
cases (principally medical and chronic) in view of the cot accommodation that may possibly be needed when a general advance is decided upon and the next great battle takes place. I regret to say that enteric fever is prevalent there and, worse to relate, seems on the increase, and as the war goes on a considerable accession in the number of victims to this terrible military scourge may very naturally be expected despite every possible sanitary precaution being taken to prevent its occurrence. As the list of enteric cases mounts up it will, if it has not already, become a serious question with our medical authorities at our hospitals on the line of communication where and how to locate these fever cases so that one and all may receive the necessary and continuous care and watching which they require. With the merely wounded it is a very different matter, for after primary and careful dressing both officers and men can be easily and safely removed by the admirably served hospital trains from the front to the base; but with enteric fever cases there are obviously reasons why this shifting process with safety to the patient or without risk to others cannot well be carried out. On the other hand, with a view to possible contingencies, no medical officer would like to have his accommodation for wounded lessened by a large number of enteric fever cases being thrown on his hands. It has been suggested that marquees should be used for their reception, but enteric fever cases could not safely be so located in a climate like this, where the daily heat is so great, the nights so cold, and where violent dust storms and other drawbacks are daily in evidence. This question, then, of what to do with our daily increasing cases of enteric and other forms of fever must inevitably, sooner or later, force itself to the front, and will no doubt be dealt with by the medical officers successfully, for they have already foreseen and recognised the extreme gravity of the situation in this war and made judicious arrangements to grapple with emergencies as soon as they arise.

FIG. 1.



View of Military Hospital at De Aar. The illustration gives a general view of the appearance of the military hospital at De Aar. The buildings [illegible] from the left of the [illegible] are as follows:—1, Surgeons' tents. 2, Wooden huts. 3, Formerly De Aar schoolhouse, now used as an enteric fever ward and for administrative offices. 4, Wooden huts. 5, Hospital orderlies' marquees.

FIG. 2.



Plan of Military Hospital at De Aar. This side of the rail all the land is used as a camping ground by the various regiments located at De Aar. 1, Administrative offices and enteric wards. 2, Officers' marquees and tents. 3, Wards with position of cots shown. 4, Wards with position of cots shown. 5, Principal medical officer's office. 6, Patients' marquees and tents. 7, Latrines. 8, Lavatories.

Let me say something about De Aar, a most important military camp about five hours' journey from the Free State border and 501 miles from Cape Town. It is a large camp, in which may be found regiments representing every branch of our military service, together with an extensive remount depot at which thousands of mules and horses are detained for supply elsewhere. The amount of work—traffic, goods, and telegraph—got through at this station is enormous, and the manner in which details are worked out reflects credit on all concerned. One has only to visit the station by day or night to comprehend the character and amount of labour necessary to avoid confusion or delay in the traffic, and it is only as this campaign proceeds, with thousands of troops passing up to the Modder or elsewhere and hundreds returning torn, wounded, and mangled from the fields of battle, that an observer realises to the full the extent which detail enters into such an undertaking as a great war. De Aar is both a receiving and a halting place and must always take a prominent position amongst the stations to be occupied by our military during the present war. A few months ago it was not of much importance, being kept up by a little farming interest located in the district and containing two general stores, one church, an hotel, and a sprinkling of small cottage tenements tenanted by the railway officials. But owing to the fact that it is a junction where several important lines meet from

Modder river, the Free State, and Port Elizabeth, while it is situated in a plain between parallel kopjes easy of defence, it has been selected and fortified as a most important strategical centre on our line of communication and bids fair to increase in size and importance, as the war proceeds. The railway station, a commodious building of brick, stands 4180 feet above sea level. The air is very dry. During the day at times the heat is oppressive, the thermometer standing in the shade as high as 104° F. Indeed, on Thursday last it broke the record by three degrees during a terrible dust-storm, which enveloped the camp for hours. As evening approaches and night comes on the temperature rapidly decreases some 40 or 50 degrees, and when darkness deepens the unclouded canopy of heaven scintillates with myriads of stars, while the cool, invigorating breezes wafted from every point of the compass make amends for the tortures of the heated day that has gone. The grape and the peach grow well, but however large or ripe they may be they do not possess the flavour of our English fruit. The water here is peculiar; it is very hard, contains a large quantity of mineral matter, and nitrates in abundance, but no nitrites. It gives all new-comers severe griping and purging, complaints which pass off in two or three days. Dilute sulphuric acid and catechu are the general remedies employed. I myself have been a sufferer for the last few days and can speak feelingly as to the distress produced. For our enteric fever cases milk is in much demand, but only a small amount of it can now be procured owing to the continued drought (over four months) which has prevailed at De Aar. Meat is lean and somewhat tough, and insipid from that cause. Bread even at the hotel table is sometimes sour. These are, after all, minor complaints, but there are others of more importance—especially the continuous winds which bring most disagreeable dust-storms to cover the tents, destroy the food, and stop our watches. Flies keep man and beast in a perpetual state of worry and discomfort. Out-of-doors we are nearly blinded with the columns of dust, and if we retire within the tent or walls eyes, ears, lips, and mouth are attacked by a very host of biting winged insects. For the species of discomforts which I have emunerated I do not think De Aar can well be beaten.

The camps of the various regiments are located on the eastern side of the railway and are exposed to the full force of these dust-storms. The men are, however, fairly healthy, one regiment which has been some weeks here having only six sick in hospital so far.

The Military Hospital (*vide* sketch and plan) is situated about half a mile N N E. of the railway station. It is composed of a large brick-built edifice together with six marquees and 36 double-walled bell tents. It is under the charge of Major Marsh, R A.M.C, who took over the main building with 92 cases on Nov. 29th last, since which time 46 officers, 1004 British troops, and 72 men of the auxiliaries have been treated at these sick quarters. The cases at present under treatment number 230 and the number of deaths up to date amount to only six, five of which were due to enteric fever, the remaining one succumbing to a gunshot perforating wound of the intestine. No officers are treated here but at the old railway hospital which is situated at the other end of the township. The military hospital can easily accommodate 300 or more cases, but two more rows of wooden huts are in course of erection, the materials having been discharged already at De Aar railway station. I regret to say that enteric fever is leaving its mark here as well as at Modder river. Captain Mackenzie of the Army Service Corps died last week from enteric fever contracted at Modder river and since then two other patients have succumbed, one of these being an officer. When the men have done their fighting and all war stimuli are removed by cessation of hostilities then enteric fever always makes its appearance to swell the casualty lists and to rob many a homestead of its bread-winner. Major Marsh, the principal medical officer here, permitted my going over and inspecting the wards and patients The sick all looked as if their wants, professionally and domestically, had been well looked after. Indeed, every man among the sick and wounded to whom I spoke expressed complete satisfaction with the kind, humane, and judicious treatment which had been received under Major Marsh and his several colleagues. The huts on the northern side are kept for the surgical cases and those on the southern side for the medical and general cases, while in the two large schoolrooms in the centre brick building enteric fever cases are treated. The various small rooms under this roof are used for dispensary, linen, and stores purposes. The earth closet system prevails, and the men's latrines are placed in the N.N.W. angle of the camp ground.

The civil practitioners deserve any amount of credit for the manner in which they have backed up the officers of the Royal Army Medical Corps, but a great deal of the detail and clerical work has had to be done by the latter in consequence of the former being perfectly fresh to the requirements of military organisation. I should like to mention that the French Society for Affording Aid to the Wounded, having its offices in Paris, have sent out to Africa no less than 45 handsome cases containing instruments, bandages, medicaments, books, writing paper, office furniture, and a host of very useful articles, for the use of our hospitals at the front. These cases each contain different articles, but one and all are of the newest and most appropriate design and are quite up to, if not ahead of, the times. Surely some public recognition should be made to our across-Channel neighbours for their very handsome and timely gifts.

There has been only one major operation at this hospital, the serious cases having been sent down to the stationary hospitals at the base. At De Aar there is an excellent operating-room, larger and better ventilated than anything which I have as yet inspected, and an x-ray room also. The burial-ground seems very well kept and looked after. I noticed six newly made graves in a row; each had a wooden tablet at the head of the grave, and at the base the names of P. J. Houden, 1st Essex; J. Langford, R F.A.; R. C. Henly, Coldstream Guards; P. E. Rees, Welsh Fusiliers; P. J. Shaw, Grenadier Guards; and Ward, R A.M.C, respectively.

Notes on Board a Volunteer Transport.

(From our own Correspondent.)

You asked me to send you a full account of the feeding of the troops on board the *Montfort*, with possible hints as to improvements for the future. I am glad that I have not to give any hints as to improvements but everything is most excellent. Instead of provisioning the ship for the troops and having the rations cooked and served by the purser's department, as is usually done, the authorities have on this occasion—perhaps because all the troops on board are, or were a short time ago, Volunteers—given the shipping company a fair sum per man per day (I believe the sum is 1*s.* 6*d.*), and owing to the generosity of the owners even this sum has been exceeded, as you can well believe after seeing the enclosed bill of fare for a Sunday and a Friday taken at random.

Sunday.—Breakfast, 8 A.M.: Irish stew, bread-and-butter, marmalade, tea and coffee, and biscuits. Dinner, 1 P.M.: Vegetable soup, roast beef and boiled mutton, cabbage, boiled potatoes, and plum pudding and sauce. Tea, 6 P M.: Cold roast beef, cold boiled ham, bread-and-butter, pickles, and jam.

Friday.—Breakfast: Labrador herrings, bread-and-butter, marmalade, and tea and coffee. Dinner: Pea soup, fish (ling) and sauce, roast beef and salt pork, haricot beans, and boiled potatoes. Tea: Smoked herrings, cold meat, bread-and-butter, biscuits, and jam.

Instead of the usual arrangement of fresh bread twice a week the men have fresh bread *always*. The owners (Messrs. Elder, Dempster, and Co.) have also given an excellent writing-case to each man and a pack of cards to each mess of 14 men, and they will shortly give them a pound of tobacco each. The men may therefore, indeed, consider themselves lucky. The troops on board consist of the battery of the Honourable Artillery Company, now known as the City Imperial Volunteer Artillery, with seven officers (including a medical officer and a veterinary surgeon), 125 men, and 114 horses; the Oxfordshire Company of the Imperial Yeomanry with three officers and 116 men, 60 horses, and one dog (a fox-hound which is the pet of the ship); and Lord Iveagh's Irish Hospital with eight officers and dressers, 51 men, and 80 mules. We are thus very well off for medical men, of whom the following is a complete list:—Dr. George Stoker, Dr. Friel, Dr. Pounden, and Captain Mould, R A M C., of the Irish Hospital; Captain Atwood Thorne, of the City of London Imperial Volunteers; and Dr. Prentice, the surgeon attached to the ship.

There has been very little illness on board. A few men have been slightly injured by the horses and mules, and as the weather has been rough there has been a certain amount of sea-sickness, but from the medical point of view there has been nothing of real interest. Some 60 men of the battery have been vaccinated, but so far only one anti-typhoid inoculation has been performed. Nearly all the men will be inoculated after we leave Las Palmas. The ship is provided with excellent refrigerators, which are worked by the Linde system, and with 30 days' fresh provisions, including fresh milk for all on board.

S.S. [illegible], Transport [illegible], nearing Las Palmas, Feb. 9th.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(Concluded from p. [illegible])

IN previous articles[1] on Lord Llandaff's report on the metropolitan water-supply we have given a summary of the recommendations at which the Commissioners arrived and we have considered in some detail the questions of control and those having reference to the difficulties of severance of the various metropolitan water companies' undertakings, as well as the opinions on the question of purchase which have been given by the outside authorities. A very large part of the report, however, has not been touched upon. It refers to financial questions and to the reasons which have led the Commissioners to recommend that the undertakings shall be bought and administered by a new Board of Control. On the question of finance the divisions under which the Commissioners considered their report were the present financial position of the water companies, the possible terms of arbitration with special reference to the contentions of the London County Council, and the results which would probably obtain in the case of purchase. The cases in which provincial water undertakings have been bought by local authorities are briefly considered and some pages of the report are devoted to a consideration of the present and prospective requirements of London with regard to water-supply; and a scheme is given with regard to the composition of the new body which the Commissioners propose should be created to carry out their recommendations. With reference to the financial position of the metropolitan water companies the Commissioners say that they have prepared a separate volume giving maps which show the area supplied by the companies and also their intakes, works, and principal mains. The volume containing these maps, plans, and diagrams has not yet been published, but the Commissioners give a good account of the financial condition, and this we think our readers should study that they may realise a little the value of the undertakings.

The ordinary stock of the water companies in 1897 had a nominal value of £10,228,548. The capital of the New River Company represented £2,019,958, and consisted of King's shares and Adventurers' shares, which are real estate, and £500,000 of new shares which were issued in the year 1866. There is no limit to the dividend which can be paid by the New River Company on either of these classes of shares. Seven other companies have £686,700 stock on which the dividend is limited to 7½ per cent.; £400,000 stock with a dividend limited to 7 per cent.[2]; and £7,121,890 stock limited to a dividend of 10 per cent. All the water stocks which are limited as to the amount of dividend paid are entitled to back dividends—that is to say, a dividend larger than the limited dividend may be declared in order to make up the deficiency of any previous dividend which has fallen short of the statutory limit. The Stock Exchange value of the £10,228,548 of ordinary stock was £32,645,169 at the end of the year 1897. In addition to the ordinary stock, in June, 1898, there was preference stock to the amount of £801,676 which was entitled to interest at the rate of 5 per cent. and 4½ per cent. There was also irredeemable debenture stock to the amount of £4,250,110, with an annual charge of 5 per cent., 4½ per cent., and 4 per cent. There was also debenture stock amounting to £1,109,950 redeemable at par at various dates between 1919 and 1922, and on this the interest payable was 3 per cent. and 2½ per cent.; and the Kent Company had a mortgage of £43,000 at 3½ per cent. The total amount of preference debenture and mortgage issues was £6,203,736. The share and loan capital together amounted to £16,432,284 and the Stock Exchange valuation was £41,705,443 in 1897. The net profits—that is to say, the profits after deducting interest on debenture and preference stocks and mortgage—amounted to £1,032,728, and the dividends on shares were £973,741. The West Middlesex Company paid their maximum statutory dividend many years ago and by the year 1897 all the back dividends were paid off. In 1867 the price of the water supplied to consumers was reduced by 5 per cent., in 1870 by 7½ per cent., and in 1891 by 10 per cent. The Chelsea Company and the Kent Company have commenced to pay off their back dividends. The Grand Junction Company paid their maximum dividend in 1880 and have done so every year since that date except in the year 1895. The Lambeth Company have paid the maximum on their 7½ per cent. every year since 1882 except in the year 1895, and they reached their maximum on their 10 per cent. stock in 1897. The East London Company and the Southwark and Vauxhall Company cannot pay their maximum dividends. The dividend paid by the New River Company was nearly 13 per cent. in the year 1897. The total amounts of the seven companies on which the maximum dividend has been reached is £4,013,230; the amount of capital on which the maximum has not been reached is £3,535,360. The back dividends claimable in March, 1897, going back to the date at which the limit of dividend was first imposed on each company, were as follows: Chelsea, £778,414; East London, £2,006,157; Grand Junction, £617,677; Kent, £189,738; Lambeth, £920,670; Southwark and Vauxhall, £1,219,932; making a total of £5,732,856. The back dividends of these six companies amount to 81 per cent. of the share capital which is £7,053,524. The companies are authorised to issue in preference and debenture stocks a further amount of £3,124,500. The Southwark and Vauxhall Company (July 25th, 1898) were authorised to issue £500,000 3 per cent. redeemable debenture stock to be spent in making reservoirs and extending mains. The West Middlesex, Grand Junction, and New River Companies were authorised by the Staines Reservoir Act of 1896 to raise £1,000,000 in debenture stock and in 1898 they were allowed to borrow a further sum of £250,000. These three authorised increases in capital account amount to £5,024,500, of which the only part yet issued is some of the Staines committee's debentures.

The Commissioners point out that there was great difficulty in obtaining an accurate account of the population supplied by the companies. According to the returns made for the year 1898 the number was estimated to be 5,819,563, of which 4,478,396 were within the county of London and 1,341,167 outside it. The area supplied in London was 120 square miles and that outside London was 230 square miles. During the year 1898 the average daily quantity of water supplied was 204,053,955 gallons. Irredeemable debenture stock of the companies amounted in June, 1898, to £4,250,110 and the annual charge for interest was £175,557. In the case of purchase the Commissioners give it as their opinion that the only way for a purchaser to deal with this stock will be to take it over from the companies. The irredeemable debenture stock they consider could not fairly be converted into redeemable stock, even if it were secured upon rates, unless the change received the assent of the stockholders. The redeemable debenture stock and the mortgages should in case of purchase be taken over with the same power of redemption as that which the companies at present possess. Preference stocks existed in the case of two companies, the Chelsea and the Southwark and Vauxhall. The interest upon them, which is 4 per cent. and 4½ per cent. respectively, has always been paid, and they are trustee stocks because the two companies have paid 5 per cent. on their ordinary stock from 1879 to the present time. It would be reasonable, the Commissioners say, to value the stock as a trustee stock on the basis of 2.75 per cent. and at this valuation the nominal amount of £801,676 would be worth £1,478,036. The Commissioners report that they cannot foresee how Parliament would deal with the different classes of stocks in the case of purchase, but for the purposes of their inquiry they assume that the stocks would be taken over as they are and that the interest charged (which amounts to £249,472) must therefore be deducted from the gross profits which would be available for the purchaser.

[1] THE LANCET, Jan. 27th (p. 253), Feb. 3rd (p. 329), and Feb. 10th (p. 407).

[2] In the year 1897 this amount was increased by £30,000.

"THE DWELLING-HOUSE FROM THE DOCTOR'S POINT OF VIEW."

ON Feb. 8th Dr. G. VIVIAN POORE delivered a lecture at Carpenters' Hall, London-wall, on "The Dwelling-house from the Doctor's Point of View."

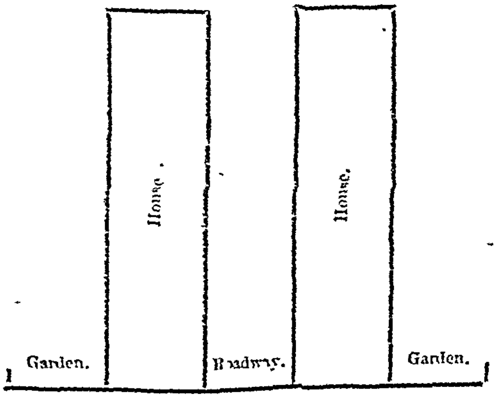
Of all the things which made for health or sickness Dr. Poore said probably the dwelling-house was the most important In answer to the question "Where will you have it, town or country?" he showed upon the screen some figures and graphic statistics which clearly proved that the country was the most desirable. From a diagram constructed from the supplement to the fifty-fifth report of the Registrar-General showing the survivals per 100,000 births in three different localities, (*a*) healthy districts of the United Kingdom, (*b*) England and Wales, (*c*) a crowded city (Manchester), it was seen that in the healthy districts out of 100,000 births 80,000 to 85,000 live to their fifth year, while in Manchester only 60,000 to 65,000 live. From life tables compiled by Dr. Tatham he showed that the expectation of life of a male child at birth in the healthy districts of England was 52 years, while in the Manchester township it was only a little over 28 years. The expectation of life was also greater at the age of five than in the first year, which showed the enormous amount of infant mortality. At all ages the expectation of life was greater in the healthy districts than in the Manchester township. At the age of 45, for instance, the expectation of life in the healthy districts was 29 years, while in Manchester it was only a little over 17 years. From mortality figures compiled by Mr. Shirley Murphy with regard to different sanitary areas of London, taking the mortality figure for London as a whole as 1000, the mortality of England and Wales was only 860, while among various districts of London the figure was 1592 in the Strand, in Hampstead 673 only, and in Lewisham 704. If, therefore, from the medical man's point of view we were able to make a choice of a residence it should be in the country and not in the town.

Another important matter was that of soil, which might be porous, as sand, gravel, or chalk, or impervious such as clay. What were the advantages and disadvantages of these different soils? The porous soils allowed the gases from the earth, one of which was carbonic acid, to rise through them. He was inclined to think that pure carbonic acid was not a very dangerous gas, and if the soil was pure the emanations from it would not be dangerous; but in a porous soil filled with impurities from cesspools or leaking sewers and putrid things buried in the soil the danger was very considerable. The house built upon a porous soil was liable to aspire the gas from the soil by reason of the heat of the fires, &c., in the house. It had, therefore, become the rule in most places to cover the foundations of a house with six inches of concrete; but the gases must have a vent somewhere, and when, as in a town, we had impermeable streets and pavements it became extra dangerous to have any vent-holes in houses because the gas, not being able to escape elsewhere, was drawn into the house. On sanitary grounds the earth round a house should be tilled. Clay soils were undesirable because they held moisture and were cold, while in bad weather it was difficult to get outdoor exercise. But the clay was impermeable and the gases which percolated through porous soil did not get through clay. As a medical man, however, he doubted *whether clay was a dangerous soil. Of course* it was to *people* susceptible to damp, but he was speaking of the average individual. The chief objection to clay was the difficulty of house-drainage. In travelling about the suburbs of London where building was going on he had seen the builders covering the foundations according to the by-laws with concrete, but the builder went into the back garden, took out the sand and the gravel, and put decomposing rubbish in their place, covering the rubbish with a few inches of soil. The object of the by-laws was thus defeated and it was another instance of the saying that although it was easy to drive a coach-and-four through an Act of Parliament it was still easier to drive a coach-and-six through by-laws.

From a medical man's point of view there was nothing more important than the aspect of a house. The best possible aspect was south-east, and if one angle only pointed north you got the sun in the house at all times of the day when it was shining. There was no doubt that sun was a very valuable thing from a health point of view. Not only did you burn less coals, but sunlight was a most important disinfectant and there was much truth in the Italian proverb, *Dove non va il sole va il medico*. Then, again, the position of the house with regard to the road was important. Here the lecturer showed on the screen several plans designed to secure the full benefit of the sun all the year round and a position with regard to the road which did not necessitate sewers being placed under the house. By having a south aspect for the front of the house the larder would be in the north, an important factor with regard to keeping food fresh.

The next point to be considered was the material of which the house should be constructed. Bricks soaked up an enormous amount of water and most kinds of stone were better, being much drier than brick. One of the warmest building materials was mud and it was the only local material in the chalk districts of England. The by-laws promulgated by the Local Government Board said that houses should be built of hard, dry, incombustible material bonded together, &c. That excluded wood. In a city like London wood was of course not to be thought of, but many urban councils had adopted these by-laws with the result that even in truly rural districts a wooden house could not be built. With regard to dryness he did not think there was a better *material than wood. Our friends in Manitoba and the back*woods lived entirely in wooden houses and to make the building of wooden houses illegal seemed to him a very strong measure indeed. There were signs that the Local Government Board was giving way on this point, and he thought it highly probable that they would eventually allow the building of wooden houses provided they were 50 feet from other buildings. He pointed out the importance of wood cottages as cheap dwellings for agricultural labourers in country districts where the building material was to hand, and suggested that the Worshipful Company of Carpenters should offer a prize for the best design for a wooden cottage.

Referring to internal arrangements he would not say that London houses could be much different from what they were, but from a medical man's point of view they were open to criticism, the most obvious being that the area of the house was too small for its cubic contents. He also criticised the trap gully, the disposition of the rooms, and the insanitary position of water-closets, as well as defective ventilation. The fact that in the early morning the smell of cooked bacon ascended from the kitchen to the bedroom was almost as important a test of improper ventilation as was the plumber's peppermint test with regard to leaky drains. Dr. Poore then dwelt on the evils of cellars and passed on to the evils wrought by the speculative builder, who took the minimum allowances of curtilage laid down in the by-laws as his maximum. One effect of the by-laws was that in the country a house could be built 100 feet high with a back-yard of only 25 feet, the width of the road between the houses being 24 feet. The effect of this was strikingly shown in a diagram similar to the following:—



Dr. Poore said that he was an advocate of allowing people to have a garden. He himself would rather live under a couple of hurdles with a garden than in the best stucco house without a garden. But the way in which some councils dealt with building operations was a great hindrance to the lovers of gardens. Some people talked of taxing gardens at their site value; that he called sanitary perdition. In assessing rates for sanitary purposes the cubic capacity of a house should be considered, but the garden ought not to be considered, for a garden was a sanitary gain to the whole community.

REPORT OF THE INDIAN PLAGUE COMMISSION UPON HAFFKINE'S ANTI-PLAGUE INOCULATION.

WE have received from the Under Secretary of State for India a copy of the fourth chapter of the forthcoming Report of the Indian Plague Commission. This chapter has been issued in anticipation of the publication of the complete Report, in recognition of the practical importance of the subject with which it deals. The chapter in question, which covers some 87 pages of foolscap size, is devoted solely to a consideration of Mr. Haffkine's method of prophylactic inoculations, or, as they are termed in the report, "anti-plague inoculations."

It is impossible to sum up in a few words the very extensive ground which this chapter covers. It may be said, however, that it is mainly a close but lucid criticism of a large mass of material, statistical and otherwise, which was placed before the members of the Commission in many different parts of India; that this is supplemented by the results of certain special observations and experiments made by the members of the Commission themselves or undertaken by others at their request; and that it ends with a number of definite conclusions and recommendations to which the consideration of this material naturally leads. It is to the latter that most readers will probably look first, and by that very large body of persons in this country who have been awaiting a definite "yes" or "no" verdict as to the value of Mr. Haffkine's method the answer required will be found in the last paragraph of this chapter of the report. "We cannot," that paragraph runs, "bring to a conclusion this consideration of anti-plague inoculation by Mr. Haffkine's prophylactic fluid without expressing our sense of the importance of the method which Mr. Haffkine has devised and of the results which have been achieved by it. The credit due to Mr. Haffkine is the greater because the difficulties with which he had to contend in this matter could only have been overcome by great zeal and endurance. Mr. Haffkine's work on anti-plague inoculation, while not based on any new scientific principle, constitutes, it seems to us, a great practical achievement in the region of preventive medicine." From these remarks it will be seen that, in general terms, the value of the method of prophylaxis in question is fully endorsed by the Indian Plague Commission. Notwithstanding the severe and searching criticism to which the method and the results claimed for it are subjected, and in spite of certain obvious defects in both (which are pointed out in detail in this chapter), the Commissioners consider Mr. Haffkine to have performed a great life-saving work in the face of almost insuperable difficulties.

The principal conclusions of the Commission in regard to the prophylactic naturally group themselves into two divisions: firstly, those concerned with the protective effect of the inoculations upon individuals and communities; and, secondly, those concerned with the feasibility of adopting a general policy of inoculation as a practical measure against the ravages of plague. We quote in full the conclusions arrived at under each of these heads.

Firstly, in regard to the protective value of the prophylactic inoculations the Commission summarise their conclusions as follows:—

I. Inoculation sensibly diminishes the incidence of plague attacks on the inoculated population, but the protection which is afforded against attacks is not absolute. On the one hand, plague has attacked persons who have undergone inoculation as many as four times in the course of two years previous to their attack. On the other hand, as many as 8 per cent. of the inoculated population may suffer from plague, as was the case in Bulsar. Many varying influences have been at work in determining the rate of attack in different places, and it is impossible to give a numerical expression for the measure of protection against attack which inoculation confers.

II. Inoculation diminishes the death rate among the inoculated population. This is due not only to the fact that the rate of attack is diminished, but also to the fact that the fatality of attacks is diminished. Here, again, no numerical expression for the amount by which the death rate is diminished can be given.

III. Inoculation does not appear to confer any great degree of protection within the first few days after the inoculation has been performed. This fact, we may note in passing, has an important bearing on the question of the risks which would be incurred by recently inoculated persons if they were left isolated in surroundings where plague [illegible] for their [illegible] to the [illegible].

IV. Inoculation confers a protection which certainly lasts for some considerable number of weeks. It is possible that it may be found to last for a number of months. The maximum duration of protection remains to be determined by further observation.

V. The varying strength of the vaccine employed has apparently had a great effect upon the results which have been obtained from inoculation. There appears to be a definite quantum of vaccine material which gives the maximum amount of protection; and it is probable that this quantum can be injected in one dose, and provided also that the protection turns out to be a lasting one, an inoculation [illegible]. The best results of inoculation will only be obtained after an accurate method of standardisation has been devised.

Secondly, in regard to the feasibility of adopting inoculation as a general plague measure the Commission formulate the following conclusions:—

1. Experience gained at [illegible] has shown that it is very [illegible] a large proportion of the inhabitants of an infected place inoculated.

2. It has been possible, where the inducement of exemption from segregation and [illegible] has been offered, to get a large proportion of the inhabitants of an infected place inoculated rapidly.

3. It has been possible in one place, Mysore city, even where no inducement that touched the great mass of the people could be offered, to get a considerable proportion of the inhabitants of an infected place inoculated rapidly.

4. It has been possible also to get a large proportion of particular communities, such as the followers of [illegible] and [illegible], to be inoculated under the influence of their leaders.

The recommendations based upon these conclusions, and on the additional "consideration that it is advisable to make the operation as effective as possible, as little inconvenient as possible to the person inoculated, and as easily carried out as possible by the inoculator," are as follows:—

I. We have already insisted on the necessity for the adoption of a standardised method of [illegible], as being essential to the attainment of the best results, both as to the protection conferred and as to the duration of that protection. We have pointed out, further, that the introduction of an accurate system of standardisation may possibly obviate the necessity of applying successive inoculations.

II. With a view to dispelling the natural fears of the people, and avoiding all unnecessary risk to the inoculated, and further, with a view to [illegible] the inoculations to be carried out with the least possible amount of after [illegible], we would further urge the necessity that stringent precautions should be taken to ensure that all the vaccine used is quite free from contamination, and we would recommend that the volume of the necessary dose should be as small as possible.

III. With a view to removing any possible ground for [illegible] the conveyance of disease by inoculation from one person to another we would recommend that the syringe should be sterilised in the presence of the person about to be inoculated.

IV. We are of opinion that inoculations under the safeguards and conditions stated above should be encouraged wherever possible, and in particular it seems to us desirable to encourage inoculation among disinfecting gangs and the attendants of plague hospitals.

Although occupying the last pages of the section of the report now issued we have quoted these conclusions and recommendations near the commencement of this notice for the reasons already stated. For the present we leave them without comment and may proceed to discuss briefly the larger mass of subordinate and detailed conclusions arrived at in the body of the report, upon which the main conclusions and recommendations just quoted are based.

The section of the report now issued opens with a brief *résumé* of the history of preventive inoculation from the discovery of small-pox inoculation down through the discovery of vaccination, the work of Pasteur upon anthrax, that of Ferran upon cholera, and the more recent work of Haffkine himself upon the last-named disease before he took up the subject of plague prophylaxis. It is unnecessary here to dwell upon this preliminary review of what is familiar to most readers who have any acquaintance at all with the history of preventive medicine. Coming to the subject of inoculation against plague it is pointed out that the first experiments in this direction were those of Yersin, Calmette, and Borrel, who in 1895 made a number of comparatively successful experiments on the production of immunity against plague in rabbits and guinea-pigs by the hypodermic injection of dead cultures of plague bacilli. It was left to Mr. Haffkine to apply successfully a similar method on a large scale to the prevention of plague in human beings.

The method followed by him is conveniently discussed under the following different headings:—

I. The method of preparing mass cultures of the plague bacillus.

II. The method of controlling the purity of those cultures.

III. The method of killing the plague bacilli with the view of converting the culture into an immunising material.

IV. The method of decanting and bottling the prophylactic fluid.
V. The method of ascertaining that the vaccine is free from contaminating micro-organisms and the precautions which are adopted for preventing the growth of such organisms.
VI. The method of standardising the vaccine.
VII The composition of the vaccine.
VIII. The volume of the prescribed dose.

As to the mode of preparing the mass cultures, the report expresses full approval of the methods adopted to avoid the use of such animal products as might be offensive to the feelings of the natives of India, and at the same time to produce a growth in mass on a liquid substratum and to provide for the efficient aeration of the cultures. Approval is also, on the whole, expressed of the second point under consideration—the method of controlling the purity of the cultures—though at the same time it is pointed out that to rely solely upon "the specular appearance of the colonies of plague bacilli, seen from behind by the reflected light through the depth of the agar," which is the method hitherto adopted, is one which, in less experienced hands than those of Mr. Haffkine, could scarcely be regarded as a trustworthy index of the purity of the culture.

The method of killing the cultures of plague bacilli hitherto practised—by subjecting them to a temperature of 65° C. for one hour—is also fully approved as being the routine method adopted by every bacteriologist for a similar object. It is, however, pointed out that Mr. Haffkine has made no experiments upon the effect of this heat, or upon the effect of the addition of ½ per cent. of carbolic acid as practised by him, upon the immunising powers of the fluid. The German Plague Commission has, however, shown that as regards the bacterial sediment in the prophylactic fluid its immunising powers are in no way diminished by the heating process, and the authors of the present report themselves have proved by experiment that the same is true of the supernatant fluid. The curious fact is added that the experiments of the German Plague Commission showed that the addition of ½ per cent. carbolic acid had no effect upon the immunising powers of a *heated* plague culture, although it completely destroyed these powers in an *unheated* culture. No explanation of this curious fact is offered nor is any attempt made to determine its significance.

The methods of decanting and bottling the fluid and of securing its sterility are naturally discussed at considerable length. The mode hitherto adopted—of storing the fluid in ordinary medicine-bottles closed by corks and sealed with sealing-wax—is one which obviously presents very great difficulties in ensuring sterility, and in spite of various methods of sterilising the bottles, the corks, and the syphon, the process of syphoning off an organic fluid such as the plague prophylactic from flasks into bottles cannot, it is found, be accomplished without admitting, in a certain proportion of instances, outside contaminations. It will be recalled that Colonel Lawrie, I.M.S., of Hyderabad, went so far as to condemn, in most unmeasured language, the entire use of the prophylactic in consequence of the contamination of a certain proportion of bottles. The members of the Plague Commission are more moderate in their criticism. They discovered by a series of accurate experiments that in some 22 5 per cent. of bottles contaminations are present. These are, in their opinion, due partly (but not "almost entirely," as Mr. Haffkine urged) to imperfections in the sealing of the bottles and partly to the method of syphoning off the fluid from the flasks into the bottles. They, further, while urging the necessity for devising some method which shall ensure the absence of such contaminations, fully admit that, from a practical point of view, the presence of these contaminations has never been shown to have such harmful results as might be, and have been, urged against them on *a priori* grounds. "We have not," they say, "had any evidence laid before us which goes to show that any serious ill consequences have resulted from the defect in sterility which was spoken of above. We made careful inquiries into this question in the various centres where anti-plague vaccinations have been performed. In the overwhelming majority of cases no evidence was adduced to show that any injurious effects had supervened upon inoculation. In a few isolated cases, however, there was evidence that abscesses had occurred in the vaccinated at the seat of injection." It is added, however, that it is impossible to assert that such abscesses, or an occasional long-continued reaction at the seat of inoculation and continuance of fever, were in truth due to these contaminations and were not merely toxic effects.

The method of standardising the prophylactic hitherto in use has been of a very simple, not to say primitive, character. It has consisted in holding one finger behind the flask containing the fluid and judging by the degree of opacity present whether the fluid was of ordinary strength, and therefore to be administered in the standard doses of two and a half cubic centimetres or of such strength as to be administered in fractions or multiples of that dose. In other words, a rough estimate of the amount of sediment (or dead bacilli) present has been taken as an estimate of the immunising powers of the fluid. A second method of estimating its powers has been by observing its effects upon the first 10 or 20 patients inoculated, the strength aimed at being such as to produce an average temperature in the persons inoculated of 102° F. The difficulties and objections in the way of both these methods are very obvious, and it is not surprising that the Commission dwell on the imperfections of both methods. The difficulties in the way of standardising a fluid of the kind and of obtaining an accurate dose of the immunising material are indeed exceedingly great. No systematic method, it is pointed out, has been hitherto practised for ascertaining the virulence of the cultures originally employed for the production of the prophylactic. Further, it is shown that, while the sediment contains the great bulk, if not the entirety, of the immunising material, the supernatant fluid may in some instances contain a considerable amount of toxins. Where very large doses of a particular sample of the prophylactic are recommended there can be no certainty that a dangerous dose of these toxins may not be introduced. No attempt, it is also pointed out, has hitherto been made to ascertain the weight of the sediment, or dead bodies of bacilli, injected in a given dose; and in view of these considerations the members of the Commission are compelled to state that they "cannot but take a serious view of the fact that in a case like the present, where the estimation of the virulence was neglected, the weight of the bacterial sediment in a prescribed dose was in some samples of the vaccine seven times as large as in other samples."

It is obvious from these statements that much yet remains to be done before the practice of inoculation with a fluid of this nature shall fulfil all the conditions which sound scientific reasoning rightly demands of it. For the present—and this in itself is no small achievement—the method may justly claim to be a practical success and very nearly, if not quite, to attain to the high ideal of a certain and safe prophylaxis against one of the most deadly of all diseases. It is, moreover, founded upon a strict scientific basis, though it is clearly in many and important details open to the charge of imperfection and empiricism. Time will doubtless remedy these defects, and it is certainly regrettable that the members of the Commission have contented themselves with merely pointing out these imperfections and the necessity for overcoming them and have not, with some minor exceptions, made any definite suggestions or recommendations as to the manner in which they should be overcome.

The statistics of the inoculations in various centres undergo strict investigation. The principal observations upon the effect of the inoculations have been made in Bombay, Daman, Lanauli, Kirki, Undhera, Hubli, Dharwar, Gadag-Betigeri, Bangalore, Karachi, Bulsar, Belgaum, and some other towns and villages. For the present we must content ourselves with this enumeration of places and with the brief statement that, while the criticism of the evidence brought forward in each of these places is largely of the nature of an academic discussion of statistical material, it ends in almost every instance with a free admission that the inoculations did largely reduce the mortality in the given place. To these criticisms and to the objections urged against Mr. Haffkine's method of expressing numerically the reduction in mortality brought about by the inoculations we may, perhaps, refer on a future occasion.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6079 births and 5750 deaths were registered during the week ending Feb. 17th The annual rate of mortality in these towns, which had been 21·2 and 22 7 per 1000 in the two preceding weeks, further rose to 25·8 last week. In London the rate was 22·9 per 1000, while it averaged 27·8 in the 32 provincial towns. The lowest death rates in these towns were 14·3 in Brighton, 15·8 in Cardiff, 18·1 in Bristol, and 18·4 in Bradford; and the highest rates were 41·3 in Wolverhampton, 41·5 in Blackburn, 42·7 in Salford, and 54·8 in Preston. The 5750 deaths in these towns included 469 which were referred to the principal zymotic diseases, against 428 and 449 in the two preceding weeks; of these 138 resulted from whooping-cough, 132 from measles, 102 from diphtheria, 33 from "fever" (principally enteric), 31 from scarlet fever, 31 from diarrhœa, and two from small-pox. The greatest mortality from measles occurred in Wolverhampton, Leicester, Salford, Oldham, Preston, and Sunderland; from scarlet fever in Burnley; and from whooping-cough in West Ham, Birmingham, Norwich, and Salford. The mortality from "fever" showed no marked excess in any of the large towns. The 102 deaths from diphtheria included 35 in London, 10 in Leicester, nine in Sheffield, five in Leeds, and five in West Ham Two fatal cases of small-pox were registered last week in Hull, but not one in any other of the 33 large towns There were eight cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Feb. 17th, against 24, 21, and 17 at the end of the three preceding weeks; no new case was admitted during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2052, against numbers decreasing from 3578 to 2089 on the 13 preceding Saturdays; 159 new cases were admitted during the week, against 190, 174, and 157 in the three preceding weeks. Influenza was certified as the primary cause of 74 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had declined from 1221 to 423 in the six preceding weeks, rose again last week to 527, and were 50 above the corrected average. The causes of 102, or 3·7 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Newcastle, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, and Sheffield

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had risen from 23·0 to 27·1 per 1000 in the five preceding weeks, further rose to 31·0 last week and exceeded by 5·2 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17·2 in Greenock and 23·3 in Aberdeen to 35·4 in Dundee and 50·6 in Perth. The 958 deaths in these towns included 24 which were referred to measles, 20 to diarrhœa, 18 to whooping cough, 11 to scarlet fever, seven to diphtheria, and two to "fever." In all 82 deaths resulted from these principal zymotic diseases, against 81, 68, and 61 in the three preceding weeks These 82 deaths were equal to an annual rate of 2·7 per 1000, which was 0·6 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of measles, which had declined from 32 to 19 in the four preceding weeks, rose again to 24 last week, and included 17 in Glasgow and six in Paisley The deaths from diarrhœa, which had been eight and 16 in the two preceding weeks, further rose last week to 20, of which seven occurred in Glasgow and nine in Dundee The fatal cases of whooping-cough, which had been eight and 14 in the two preceding weeks, further rose to 18 last week, and included 10 in Glasgow, four in Aberdeen, and two in Paisley. The 11 deaths from scarlet fever showed an excess of eight over the number in the preceding week, and were all registered in Glasgow. The fatal cases of diphtheria, which had been nine and none in the two preceding weeks, rose again last week to seven, of which three were recorded in Glasgow and three in Edinburgh The deaths referred to diseases of the respiratory organs in these towns, which had been 212 and 242 in the two preceding weeks, further rose last week to 325, and exceeded by 40 the number in the corresponding period of last year. The causes of 47, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined from 50·3 to 29·7 per 1000 in the six preceding weeks, rose again to 42·4 during the week ending Feb. 17th. During the past four weeks the death-rate in the city has averaged 36·6 per 1000, the rate during the same period being 21·3 in London and 25·5 in Edinburgh. The 284 deaths registered in Dublin during the week under notice exceeded by 85 the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against 12 and 17 in the two preceding weeks; of these five resulted from whooping-cough, three from diphtheria, three from "fever," two from diarrhœa, one from measles, and one from scarlet fever. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 1·9 in London and 1·0 in Edinburgh. The deaths from whooping cough, which had increased from one to five in the six preceding weeks, were again five last week. The fatal cases of diphtheria, which had been three and five in the two preceding weeks, declined again to three last week. The deaths referred to "fever," which had been two and none in the two preceding weeks, rose last week to three. The two fatal cases of diarrhœa corresponded with the number in each of the two preceding weeks. The mortality both from measles and from scarlet fever showed a decline from that recorded in the preceding week. The 284 deaths in Dublin last week included 40 of infants under one year of age and 81 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were in excess of the numbers recorded in the preceding week. Ten inquest cases and eight deaths from violence were registered, and 95, or one-third, of the deaths occurred in public institutions. The causes of 18, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1900.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during January in each of the 43 sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·0 per 1000 of the population, estimated at 4,589,129 persons in the middle of this year. In the three preceding months the rates had been 14·4, 12·6, and 8·8 respectively. The rates were considerably below the average in St. George Hanover-square, Westminster, St. James, Westminster, Strand, City of London, St Olave, Southwark, and Woolwich sanitary areas; while they showed the largest excess in Bethnal Green, St. Saviour, Southwark, Bermondsey, Wandsworth, Lewisham, and Plumstead. 21 cases of small-pox were notified in London during January, of which 11 belonged to Hackney and two each to Fulham, Shoreditch, and Bethnal Green sanitary areas; 20 small-pox patients were admitted into the Metropolitan Asylums Hospitals during the month and 21 remained under treatment on Saturday, the 3rd inst. The prevalence of scarlet fever showed a further decline from that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Bermondsey Wandsworth, Greenwich, Lewisham, and Plumstead The Metropolitan Asylums Hospitals contained 2126 scarlet fever patients at the end of January, against 3406, 3343, and 2797 at the end of the three preceding months; the weekly admissions averaged 180, against 426, 304, and 197 in the three preceding months The prevalence of diphtheria showed a further slight decrease from recently monthly numbers; the disease was proportionally most prevalent in Newington, Bermondsey, Wandsworth, Camberwell, Lewisham, and Plumstead sanitary areas. There were 1572 diphtheria patients in the Metropolitan Asylums Hospitals at the end of January, against 1687, 1718, and 1679 at the end of the three preceding months; the weekly admissions averaged 189, against 258, 227, and 184 in the three preceding months The prevalence of enteric fever in London showed a slight decline from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, Bethnal Green, St. George-in-the-East, Poplar, Rotherhithe, and Lewisham The Metropolitan Asylums Hospitals contained 289 enteric fever patients at the end of January, against 341, 460, and 406 at the end of the three preceding months, the weekly admissions averaged 40, against 58, 76, and 52 in the three preceding months. Erysipelas was proportionally most prevalent in St. Giles, Clerkenwell, Bethnal Green, Mile End, Old

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JANUARY, 1900.

(Specially compiled for THE LANCET.)

Sanitary Areas.	Estimated population in the middle of 1900.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.†	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

Southwark, and Lewisham sanitary areas The 24 cases of puerperal fever included three in Lambeth and two each in Kensington, Hackney, Bethnal Green, Poplar, Newington and Wandsworth sanitary areas

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the various sanitary areas in which the patients had previously resided During the five weeks ending Feb 3rd the deaths of 12 027 persons belonging to London were registered, equal to an annual rate of 27 3 per 1000 against 18 5 17 6 and 27 3 in the three preceding months The lowest death rates last month in the various sanitary areas were 13 5 in Woolwich, 19 6 in Hampstead 20 9 in St Giles 21 3 in Stoke Newington, 22 0 in Hammersmith and 22 1 in Wandsworth, the highest rates were 38 7 in St Martin in the Fields 39 1 in City of London 40 8 in St Luke, 43 5 in Holborn and in St George Southwark, and 57 1 in Lewisham During the five weeks of January 815 deaths were referred to the principal zymotic diseases in London, of these 231 resulted from measles, 35 from scarlet fever, 225 from diphtheria, 181 from whooping cough 86 from enteric fever, 57 from diarrhoea and not one either from small pox from typhus, or from any ill defined form of continued fever These 815 deaths were equal to an annual rate of 1 9 per 1000, against 1 8 1 9 and 2 1 in the three preceding months No deaths from any of these diseases was recorded last month in Strand sanitary area, among the other sanitary areas they caused the lowest death rates in Hammersmith St James Westminster, Hampstead, St Giles and City of London and the highest rates in Fulham Clerkenwell St Luke, Newington and Bermondsey The 231 deaths referred to measles were slightly below the average number in the corresponding periods of the ten preceding years, this disease was proportionally most fatal in Fulham, Chelsea Islington, Newington Battersea, and Plumstead sanitary areas The 35 fatal cases of scarlet fever were as many as 57 below the corrected average number, the greatest proportional fatality from this disease occurred in Paddington Fulham Marylebone Islington Shoreditch, and Limehouse sanitary areas The 225 deaths from diphtheria were slightly in excess of the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in St Luke, St George Southwark Newington, Bermondsey, Camberwell and Lewisham The 181 fatal cases of whooping cough were 164 below the corrected average number, this disease showed the highest proportional fatality in Westminster Hackney Clerkenwell, Bethnal Green Poplar, and Greenwich sanitary areas The 88 deaths referred to enteric fever were 29 in excess of the average number in the corresponding periods of the 10 preceding years among the various sanitary areas the highest proportional mortality from fever occurred in Fulham, Westminster, St Pancras, Mile End Old Town, St Saviour Southwark, and Wandsworth The 57 fatal cases of diarrhoea were slightly below the corrected average, this disease was proportionally most fatal in Fulham, St George Hanover square St Pancras and Newington sanitary areas In conclusion it may be stated that the aggregate mortality from these principal zymotic diseases in London during January was nearly 20 per cent below the average

Infant mortality in London last month measured by the proportion of deaths of children under one year of age to registered births was equal to 143 per 1000 The lowest rates of infant mortality were recorded in Hammersmith St James Westminster, Marylebone Hampstead, St Giles Strand and St Olave Southwark and the highest rates in Westminster, Holborn City of London, Limehouse St George Southwark and Lee sanitary areas

Influenza was stated to be the primary cause of 1125 deaths in London during the five weeks ending Saturday, the 3rd inst the corrected average number in the corresponding periods of the 10 preceding years being 315 Among the various sanitary areas the greatest proportional mortality from influenza was registered in Chelsea Hampstead Stoke Newington Greenwich, Lewisham Lee and Plumstead In addition to the 1125 deaths directly attributed to influenza there were 235 cases in which it was stated to be a contributory cause of death The deaths referred to diseases of the respiratory organs last month numbered 3865 and showed an excess of 744 over the corrected average

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

Surgeon A G Fratment is lent to Yarmouth Hospital for survey of stores

ROYAL ARMY MEDICAL CORPS

Major M. F Yarr from the Seconded List, to be Major, vice T Dorman, deceased.

Major J S Edye and Major J Moir have joined at Woolwich

The following officers are ordered to the front —Major T P S Hayes appointed to No 7 General Hospital; Lieutenant D Harvey to No 24 Field Hospital, Lieutenant A F Carlyon to No 5 General Hospital, and Surgeon Lieutenant J Clerke Militia Medical Staff Corps, to No 5 General Hospital

THE IMPERIAL YEOMANRY

To be Medical Officer, with the temporary rank of Captain I A Hadley

VOLUNTEER CORPS

Artillery 1st Ayrshire and Galloway Surgeon-Lieutenant H A Lattullo resigns his commission 1st Caithness Samuel Davidson to be Surgeon Lieutenant *Rifle* 8th *Volunteer Battalion the Royal Scots* (*Lothian Regiment*): The undermentioned Surgeon Lieutenant-Colonels resign their commissions with permission to retain their rank and to wear the uniform of the battalion on their retirement —A Ballantyne and C. J Allan The undermentioned Surgeon Lieutenants to be Surgeon-Captains —G Melville and J Cameron 2nd Volunteer Battalion the Royal Fusiliers (City *of London Regiment*) Lloyd John Hollis Oldmeadow to be Surgeon Lieutenant 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment William Edward Manderson Corbett to be Surgeon Lieutenant 2nd Volunteer Battalion the Suffolk Regiment *Sidney Hillier to* be Surgeon Lieutenant 1st Volunteer Battalion the Royal Welsh Fusiliers Surgeon Captain John Edward Henry Davies resigns his commission and is appointed Captain, Surgeon Lieutenant R Drinkwater to be Surgeon Captain 2nd Volunteer Battalion the East Lancashire Regiment Surgeon Lieutenant C E R Bucknill to be Surgeon Captain

TRANSVAAL WAR NOTES

The following is a list of officers of the Royal Army Medical Corps who were members of the staff of the Royal Victoria Hospital, Netley, or who have passed through the Army Medical School since the commencement of the war and who are now serving in South Africa.—Colonel W. T Stevenson Professor of Surgery, Army Medical School principal medical officer, lines of communication, Lieutenant-Colonel M D O Connell, No 2 General Hospital, Major G H Sylvester, secretary to principal medical officer, lines of communication, Major J Gibson, No 5 General Hospital, Major F Daly, Field Hospital, Major I Paterson 1st Corps Field Hospital, Major M O C Drury, Langman Field Hospital, Captain I W Beggie 1st Corps Field Hospital, Captain W T Mould Iveagh Hospital Ship, Lieutenant W Jagger, No 1 General Hospital (x rays), Lieutenant R H Lloyd, 1st Corps Troops Field Hospital, Lieutenant F Harvey, 2nd Middlesex Regiment, Lieutenant C E Trimble, 37th Field Company, Royal Engineers, Lieutenant H S Roch, No 15 Bearer Company Lieutenant P S O Reilly 2nd Corps troops Field Hospital; Lieutenant H C R Hime, No 6 General Hospital Lieutenant E McDonnell, No 7 General Hospital, Lieutenant A M McLaughlin, 1st King's Own Borderers, Lieutenant F H Merry, 2nd Hampshire Regiment, Lieutenant R I Davies No 9 Company Royal Engineers, Lieutenant C S Smith, 2nd South Wales Borderers, Lieutenant C R Evans 2nd North Stafford Regiment, and Lieutenant J M Quddon Fletcher, 7th Infantry Division

A hospital corps of 57 Irishmen has left New York for service with the Boers under the American Red Cross Flag

The Western Counties Association for providing convalescent homes for the South African wounded (working in connexion with the Soldiers and Sailors' *Help Society*) has raised nearly £1200 It has been decided to take 10 beds at the Combe Down Home and three at the Weston super Mare Sanatorium

The committee of Westminster Hospital have granted leave of absence to Mr. Charles Stonham, Dr. Purves Stewart, and Mr. William Turner. Substitutes will be appointed in their absence in order that the public may not suffer.

The medical staff of the Princess Christain Hospital, which is shortly to proceed to South Africa, has largely been chosen from members of the Bristol Medical School. As this is the only hospital going out in which a provincial medical school is so represented, the medical students organised a dinner which was given on Feb. 17th. Mr. Paul Bush and the other members of the staff, including Mr. Flemming, Mr. Pearse, and Mr. A. B. Cridland, together with the donor of the hospital, Mr. Alfred Mosely, were the "guests of the evening." The dinner, which was very successful, was largely attended by the medical practitioners of Clifton and Bristol and their friends.

Dr. J. Bruce (civil surgeon) left in the *Gascon* on Feb. 17th for South Africa. Mr. J. G. Wallis (civil surgeon) also left for the front in the *Guelph*. On the same day No. 20 Field Hospital of the Royal Army Medical Corps, in charge of Major Ritchie, R.A.M C., left in the *Sicilian*.

It is an excellent and happy idea to associate the Indian dhoolie bearers with the benefits of the Royal Army Medical Corps Fund and to make them participators in its benefits. Officers of the Royal Army Medical Corps have had many opportunities of judging of the work of these men. They really render invaluable services which do not stand out so prominently with the public as they deserve, for however quietly and unassumingly performed they *nevertheless frequently* make calls upon the courage, self-reliance, and coolness of those who have to carry them out on the battlefield and often under very trying circumstances. The Indian dhoolie bearers are, as a rule, devoted and fearless in their efforts to strip the battlefield of its wounded and carry them to positions where their wounds can be properly cared for. The services which these men have rendered to the British soldier in this respect in our Indian campaigns and now in South Africa thoroughly merit recognition. It is but right and fitting, therefore, that when they return to their native villages they should be able to feel, and to tell the natives of India, that this nation was not unmindful of the services which they rendered to the British army in South Africa.

On Feb. 21st the Duke of Cambridge inspected the Langman Field Hospital at the headquarters of the St. George's Rifles in Dover-street, W. The hospital, which has 100 beds, leaves in the *Oriental* on Wednesday next. As we have already announced, Mr. Robert O'Callaghan is chief civil surgeon, Mr. C. Gibbs surgeon, Dr. H. J. Scharlieb surgeon and anæsthetist, and Dr. Conan Doyle physician; Mr. Hackney, Mr. Turle, Mr. Blasson, Mr. Mayes, and Mr. Burton, senior students and dressers at University College Hospital, will act as dressers; while Major M. O'C. Drury, R.A.M.C., has been appointed by the War Office as army medical officer in charge.

All the details of the Imperial Yeomanry Hospital will, it is hoped, have been despatched by to-day (Feb. 24th) and the arrangements for the field hospital and bearer companies are making rapid progress.

The Imperial War Fund have forwarded £200 to Netley Hospital for the temporary assistance of discharged disabled soldiers.

A provisional committee for the Welsh hospital for South Africa has been formed, which includes among its members Sir John Williams, Dr. F. T. Roberts, Dr. Isambard Owen, Mr. Edmund Owen, and Professor Thomas Jones. The organising secretary, Professor Alfred Hughes, of King's College, will receive donations at 7, Chester-terrace, Regent's-park, N.W. Sums amounting to nearly £1000 have been already promised.

Captain J. E. C. Canter, R.A.M.C, and Lieutenant Goddard, R.A.M.C., were both wounded near Paardeberg during Lord Roberts's advance between Feb. 16th and 18th.

Volunteer Medical Staff Corps.

At the invitation of Surgeon-Lieutenant-Colonel J. Edward Squire the friends of the London Companies of the Volunteer Medical Staff Corps mustered in large numbers on Feb. 17th at the head-quarters of the corps in Calthorpe-street to witness the presentation of prizes by Surgeon-General H. S. Muir, Deputy Director-General, Army Medical Service Corps Surgeon-Lieutenant-Colonel Squire was able to state that 110 recruits had joined since the end of the last volunteer year when the strength of the corps was 429. Efforts were being made to furnish the corps with its own transport. The Royal Veterinary College students had shown such interest in their transport section that it was believed they would be able to draw all the men they wanted from that college. 74 of their men out of 450 had volunteered for service when the South African war broke out and he trusted that the Volunteer Act would be altered to permit of Volunteers going to the front. Surgeon-General Muir having distributed the prizes Surgeon-Major V. Matthews moved a vote of thanks, which was seconded by Surgeon-Captain J. Harper. Surgeon-General Muir, in acknowledging the vote, said that he had had the pleasure of being at the inspection last summer and was then highly delighted with what he saw in the way of work. With regard to the transport he was deputed by his chief, the Director-General, to say that he sympathised with them in the matter, and that it was his intention to try to obtain for them a better grant than what was now the case. He had every reason to suppose that his recommendation would be acceded to. With regard to the offer of Volunteers for active service it must be remembered that the situation was new. It was the first occasion on which such a large force had left the country and it must also be remembered that the motto of the Volunteer force was "Defence, not defiance." It had not been contemplated that Volunteers should go on a campaign abroad, but things, however, had changed and now the Volunteers were to have a chance at the front. With reference to the Volunteer Medical Staff Corps the warrant that was now coming out, though perhaps not satisfactory to everybody, would set things right. Those men who wished to go to the front would have an opportunity in the near future, and he hoped that he might say on behalf of the Director-General that they would sooner have them than anyone else. He had heard it said that the St. John Ambulance men had been preferred to them, but that was not so. The officials had not the authority to take the men of the Volunteer Medical Staff Corps, but he hoped that the authority was now coming. Some misunderstanding had arisen in regard to the strictness of the medical examination, but that must be fairly strict and they could not relax it altogether. He believed that some men had been disappointed at being rejected, but possibly when the rules were slightly relaxed, as they would be all round, these men might have a chance of distinguishing themselves in South Africa.

Volunteer Ambulance School of Instruction.

The spring class of the School for Stretcher Bearers held at Queen's Hall, James-street, Buckingham-gate, the head-quarters of the Queen's Westminster Rifle Volunteer Corps, by kind permission of Colonel Sir Howard Vincent, K.C.M.G, C.B., M.P., is now full. The officers' class will be held at the head-quarters of the 20th Middlesex (Artists) Rifle Volunteer Corps, Duke's-road, Euston-road, by kind permission of Colonel R. W. Edis, V.D., commencing on May 7th, a further notice of which will appear later. During the absence in South Africa of Surgeon-Captain R. R. Sleman, S.M.O.C.I.V., Surgeon-Captain E. M. Callender, Prince of Wales's Own 12th Middlesex (Civil Service) Rifle Volunteer Corps, is detailed as Adjutant to the school.

Royal Army Medical Corps Fund.

A local committee is being organised in Birmingham in support of the Royal Army Medical Corps Fund and a meeting of medical practitioners and the lady members of their families will be held on Monday next, the 26th inst., at 4 P.M. in the Medical Institute.

Reported Murder of an Army Medical Officer.

Major Walter Kiddle, R.A.M.C., is reported to have been murdered at Monghen by the Was tribe while engaged with the Burmo-Chinese Boundary Commission.

Taunton and Somerset Hospital.—The annual meeting of this institution was held on Feb. 8th under the presidency of Colonel Welby, M.P. The medical report stated that 777 in-patients had been admitted. The financial statement showed that there was a deficit on the year of £1777 which had arisen partly through exceptional expenditure on the laundry and re-flooring the wards, and also to the fact that the amount received from donations and bequests had fallen off considerably. The fund raised in memory of the late Colonel Chard, V.C., had been increased to £909. It was decided to sell stock of the value of £1000 to meet the deficiency in the accounts. The committee decided to offer 10 beds for the use of soldiers wounded in South Africa.

Correspondence.

"Audi alteram partem."

"SOME POINTS IN THE NATURAL HISTORY OF UTERINE FIBROIDS."

To the Editors of THE LANCET.

SIRS,—In your issue of Jan. 20th last is an interesting paper bearing this title and written by Dr. Champneys. The eminence of the author and his impartial judgment are likely to make these *statistics for* some time to come the standard of comparison when considering the question of operation. As I read the paper the general impression left by the figures is to show the extraordinarily small fatality of fibroids of the uterus and the high death rate that *follows* the operation of hysterectomy for their removal.

Dr. Champneys truly observes that the arguments that apply to the operation of ovariotomy cannot be urged for hysterectomy, for, whereas the natural termination of most ovarian tumours is in death, with rare exceptions fibroid *tumours do not end fatally. Speaking generally, therefore,* it is not necessary to life to remove them. With this I agree. A large number of fibroids are small, give no inconvenience, and show no tendency to increase. In such cases obviously no operation is needed and, I should imagine, is rarely performed. There is another class of cases in which the fibroid tumour is actually causing death from obstruction or acute peritonitis. In these cases notwithstanding the removal of the tumour, the patient may die from the obstruction or peritonitis previously existing. Now, it is obvious that in considering the mortality of the operation such cases must be excluded. Excluding, then the simple cases of fibroid causing no trouble and in which no operator would interfere and admitting that occasionally *from* sloughing or obstruction an operation is the only resource there remains a considerable number of cases in which without immediately threatening life, the tumour owing to its size the hæmorrhage it produces its pressure on other organs, and its rapid increase, *must seriously interfere* with health and the enjoyment of life. In this class of case whether or not hysterectomy is advisable must depend on the risk of the operation itself. If the interference with health is considerable and the risk slight a patient would naturally desire an operation. On the contrary should the risk of the operation be great and the ill health produced by the tumour inconsiderable it might be right to refuse an operation. It is therefore in this class of case that the *mortality from* the operation has to be considered. As stated by Dr. Champneys there is a difficulty in obtaining statistics for comparison, *for* the practice at the London hospitals somewhat differs. At some hospitals the operation is only undertaken when the tumour itself is formidable *or producing* serious complications. The operation in these cases is generally difficult and prolonged and the *mortality* will be high. *In other* hospitals a wider scope is given to the class of case considered suitable for removal consequently the cases will be simpler and less complicated and the mortality lower.

The special object in addressing this letter to you Sirs is to point out that the high mortality referred to by Dr. Champneys in his tables *cannot* be accepted in its crude form without some further explanation or relied on as a true index of the risk involved. It is true that Dr. Champneys explains in one portion of his paper that the figures given do not necessarily mean deaths from the operation but he does not make this point sufficiently clear for he states immediately below the table (page 149 line 4) that he takes these statistics "as a basis for arriving at the mortality from operations on *fibroids*." *As to the details of the* operations referred to at other hospitals I am unable to speak but as regards St. Bartholomew's I have before me the details of 11 of the deaths referred to in his tables and I would call attention to the following four cases amongst these.

CASE 1.—A woman, aged 49 years, was admitted *into* the women's ward St. Bartholomew's Hospital with symptoms of peritonitis a rapid feeble pulse and constant vomiting. The abdomen was *tight and enormously* distended with a fluid tumour. The skin over an area the size of the hand above the most prominent part of the tumour was gangrenous and *sloughing*. The tumour was considered to be ovarian, but the patient's general condition was so grave as to make an immediate operation impossible. The tumour was aspirated as a palliative. 16 pints of purulent fluid were drawn off. After the tapping she rallied considerably and six days later an abdominal section was performed. The tumour proved to be an enormous fibro cystic tumour lying between the layers of the broad ligament with a large quantity of pus in the main cyst. It was dissected out with difficulty, and found to be connected with the uterus by a narrow pedicle which was ligatured. Hysterectomy was not performed, she died on the following day. The solid part of the tumour weighed 13 lbs.

CASE 2.—A female aged 41 years, gave the following history. 12 days previously while at stool she was seized with violent abdominal pain followed by vomiting and shivering. When admitted she looked ill, with a flushed face, anxious expression, a rapid pulse and raised temperature. The abdomen was tender much distended, and tympanitic. Abdominal section was performed the next day. Some of the coils of intestine were found glued together with lymph and there was a large quantity of blood clot. The cause of the bleeding and peritonitis was a fibroid tumour with a long stalk attached to the fundus of the uterus. This had become partially twisted. The tumour was removed but hysterectomy was not performed. The lymph and *blood clot* between the coils of intestine were washed away as far as practicable. The patient however, gradually grew worse and died 40 hours later.

CASE 3.—A woman aged 29 years, was intensely anæmic from profuse losses at her periods. The pelvis was blocked *by a tumour which rose two thirds of the way* to the umbilicus. On opening the abdomen the uterus which had some large fibroid nodules on it was pushed right up out of the pelvis by some tumours growing beneath. Hysterectomy was first performed with comparative ease on account of the way in which the body of the uterus was pushed up. The tumour on the left side was next removed. This proved to be a pyosalpinx intimately connected with the rectum with which it had probably communicated. Anyhow the rectum was damaged and it was sewn up with Lembert sutures. The tumour on the right side was then examined and was found to be an adherent dermoid cyst of the right ovary. This was removed. The triple operation lasted one and three-quarter hours, the greater part of the time being occupied in dealing with the pyosalpinx and injured rectum. The patient was greatly collapsed she never rallied and died the same night.

CASE 4.—A woman aged 44 years was admitted for *profuse menstruation and pain*. On the abdomen being opened a large cyst was found situated between the layers of the broad ligament. The uterus was intimately connected with the cyst. The cyst was dissected out with considerable difficulty and much loss of blood. One side of the uterus which was enlarged showed a raw bleeding surface, the hæmorrhage being difficult to deal with it was then decided to remove the uterus as the best means of arresting it. The uterus contained two fibroids one the size of an orange one half the size. The patient was much collapsed from the prolonged operation and hæmorrhage and never rallied and died 19 hours afterwards.

I think that these four cases should not have been included *without an explanation in* a table showing the mortality from abdominal hysterectomies for fibroids, for in the first two cases no hysterectomy was performed, the removal of the pedunculated tumours merely failing to save the patients, while in the two latter hysterectomy was only an incident necessitated during the removal of other coincident disease.

I remain Sirs, yours obediently,

HARRISON CRIPPS.

Stratford place Oxford street W. Feb. 12th, 1900.

AUGUSTE COMTE.

To the Editors of THE LANCET.

SIRS,—You have an annotation in THE LANCET of Feb. 10th on Auguste Comte founded on an interesting article by Dr. W. W. Ireland with respect to the philosopher's mental aberration. Any mention of his insanity has always been disagreeable to his followers. When a few years ago I communicated to THE LANCET a short account of my colleague James Hinton and said, "what the world called madness had often been associated with genius, as in the cases of Irving, C [illegible] Comte, I got an immediate reply from the late Richard Congreve, one of Comte's chief apostles, as follows:—

17, Mecklenburgh-square, Jan. 8th, 1876.

DEAR SIR,—Forgive me if, having known Mr. Hinton slightly and M. Comte much better, I object to your putting them in juxtaposition as you do in this week's LANCET. Press the former in argument and you got deeper into obscurity, or ask him a question as to what he held on a certain point, and in like manner he seemed able to hold both "yes" and "no" upon it. I will venture to say that no one ever carried away that impression from Comte. His profound mathematical training had given him the clearness and precision on all subjects which Mr. Hinton so singularly wanted and which I think had you known Comte you would have valued. If I may be allowed to state the inference I drew from the impression produced in my mind by reading what you write whenever I meet it I often think you come nearer the positive statements than any other physician. Especially do I remember a vigorous elimination of that foolish conception of nature which so many bore us with.

Pray excuse my freedom in writing to one who is a perfect stranger to me.

Yours faithfully,
RICHARD CONGREVE.

Dr. Wilks.

I had the pleasure of making Comte's acquaintance when dining with a friend at Paris in the spring of 1851. I found him very quiet and unpretentious; there was nothing striking in his appearance; he had a shelving forehead and did not look like a man of power. He was then giving a course of gratuitous lectures on Sunday mornings styled, "Cours philosophique sur l'histoire générale de l'humanité." I went to hear the first one on "Théorie fondamentale de la nature humaine, d'après la doctrine subjective du cerveau." On his syllabus he had his usual motto, "Ordre et progrés—vivre pour autrui." In the following year Louis Napoleon proclaimed himself Emperor and Comte's public life came to an end, but he did not die until five years afterwards.

I am, Sirs, yours faithfully,
SAMUEL WILKS.

Grosvenor-street, Feb. 17th, 1900.

"THE PHYSIQUE OF THE BOERS."

To the Editors of THE LANCET.

SIRS,—Your sane and timely article on British physique as compared with that of the Boers ought to be pressed further. Imperialists and humanitarians must unite in desiring for every British citizen a body which has been developed to the utmost perfection whereof it is capable. Town life is a bar to this, but town life has proved itself so attractive that we must accept it as inevitable; what is required is that to the town-dweller there shall be assured all the healthy conditions of country life. The problem may seem insoluble to many; if so, they will be glad to learn that a solution has been thought out and is being shaped for experiment. Mr. E. Howard has devised a garden city which combines the good points of both town and country. It seems to me and to others who have studied his book a feasible plan. In the *Medical Magazine* for this month I have published a short paper on this practicable city of health; but I would urge every sanitarian and philanthropist to study for himself Mr. Howard's notable book. He will feel inclined to carp at details, no doubt. Then let him join the Garden City Association and aid in perfecting a noble and salutary conception.

This heartbreaking war ought surely to issue in a wiser and healthier national life. That it may do so we as a profession must strive to turn the minds of the people from revenge abroad to reform at home, from covetousness to righteousness, from the mote in the eye of another nation to the beam in the eye of our own.

I am, Sirs, yours faithfully,
W. WINSLOW HALL.

Feb. 20th.

*** Dr. Hall will observe that the article in question was from a correspondent. We agree with the writer in the main.—ED. L.

"NOT THE DISEASE ONLY BUT ALSO THE MAN."

To the Editors of THE LANCET.

SIRS,—Your annotation on the Shattock lecture for 1899 on this subject interested me exceedingly. That the physician has to study not disease *per se* but the diseased man is a truth which took us some 22 centuries to learn but which Aristotle evidently knew Anno 350 B.C., for he writes: "Φαίνεται μὲν γὰρ οὐδὲ τὴν ὑγίειαν οὕτως ἐπισκοπεῖν ὁ ἰατρος, ἀλλα τὴν ἀνθρώπου, μᾶλλον δ᾽ ἴσως τὴν τοῦδε, καθ᾽ ἕκαστον γὰρ ἰατρευει." Until 50 or 60 years ago disease was regarded as an entity distinct from the body, to be expelled from it by drugs, like a tapeworm, whereas we now regard it as *a state* affecting the entire man, body and mind, structure and functions, so that it would be more correct to say that he *is* the disease than that he has "got" it. And as this state varies with the constitution, inherited tendencies, antecedents and surroundings of the man, it requires a corresponding variety of treatment. Hence the necessity of having the patient before us to study, and the impossibility of advising and prescribing at a distance; also the folly of supposing that for every disease and symptom there is a specific remedy. The wise physician adapts his treatment to each patient's peculiarities; to one he may give a certain drug, to another with the same disease a different one, and to a third no drug at all; in short, "καθ᾽ ἕκαστον ἰατρευει." A man who had a pain at the vertex was told and believed that he had softening of the brain; after taking many drugs, finding he was no better he consulted the late Sir William Gull, in whom he had great faith, and who assured him that he had no brain disease and that a week's change and rest from work and worries would cure him. This assurance alone cured him at once. A young lady who apparently vomited everything she took and was treated for gastritis and gastric ulcer by several medical men, who gave her all the usual drugs, at last consulted a physician who ascertained that she had been thwarted by her father in love and religion. He compelled her to give up her lover, and afterwards refused to allow her to enter a convent. Removal from home and father to friends at the seaside cured her completely without any drug whatever. A medical man, who has had many years' practice and experience, finds out that symptoms such as vomiting may be the result of a great variety of causes, each calling for special treatment, and he naturally feels insulted when American manufacturing chemists send him pamphlets, as they do almost every week, professing to teach him therapeutics, giving him prescriptions (into which certain advertised specialities enter) for every disease and symptom under the sun, and testimonials from a vast number of M.D.'s, *always American!* I treat these pamphlets as I should Mother Siegel's and throw them at once into my waste-paper basket.—I am, Sirs, yours faithfully,

D. HOOPER, B.A. Cantab., M.B. Lond.,
Physician to the Surrey Dispensary.

Trinity-square, S.E., Feb. 20th, 1900.

"THE SO-CALLED DANGER FROM THE USE OF BORIC ACID IN PRESERVED FOODS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 6th (p. 13) there appeared an article under the above heading by Dr. Oscar Liebreich, from which I quote the following: "During these 10 years of experience of practising physicians there has not been forthcoming any instance of injury to health from the administration of small doses of borax and boric acid." I frequently order boric acid in from 10 to 20 grain doses three times a day, especially in bladder cases, and with a considerable experience of the drug thus administered I can say that in the majority of cases a detrimental effect on the general health becomes apparent, usually within a week or 10 days. The symptoms that develop are those of dyspepsia more or less acute, not bad enough to confine the patient to bed or even to the house, but still sufficient to make life miserable. So often has this been observed that I am in the habit of warning people when they are taking boric acid of the possible occurrence of such symptoms and that their onset must be regarded as the signal for its discontinuance. On discontinuance the symptoms quickly subside, to reappear when the patient has resumed the use of the drug.

I remain, Sirs, yours faithfully,
A. R. ANDERSON, F.R.C.S. Eng.,
Surgeon to the General Hospital, Nottingham.

Feb. 20th, 1900.

THE NORWEGIAN EXPERIMENT OF NOTIFICATION OF VENEREAL DISEASES.

To the Editors of THE LANCET.

SIRS,—Among other schemes for the prevention of contagious diseases Norway has, since 1860, included in the list of notifiable diseases those of gonorrhœa, soft sore, and syphilis. I have just received from Dr. Boutzen of Christiania, Inspector for all Norway, a copy of the law of 1860, which empowered plans to be framed for the notification of these maladies. This sanitary law of 1860 enjoins on all practitioners in Norway to declare to the Sanitary Commission all cases of contagious disease, among which are also enumerated venereal diseases. These last are to be notified without indicating the name or residence of the patient. Hence, there has existed in Norway since 1860 a comparative statistical account of these diseases, which is, it seems to me, very interesting.

From the year 1860 up to 1879 soft sores were not separated from syphilis in the statistical reports, and therefore Dr. Boutzen commences his statistics with the year 1879. In that year there occurred in the city of Christiania, with a population of 117,000, 1127 notified cases of gonorrhœa, 314 cases of soft sore, and 365 cases of syphilis, besides 36 cases of hereditary syphilis. Taking all these venereal contagions together they amounted to 1·58 per cent. of the population in 1879 At that date, and up till the year 1888, the Parisian system of the obligatory examination of prostitution was in force, as I heard long ago from Professor W. Boeck when he visited London. Owing to discussion in this and various other European countries the French system was given up in 1888, but since then the notification of all cases of venereal diseases has been kept up. In 1887, the last year of the French *régime*, there were in Christiania, in a population of 136,000, 930 notified cases of gonorrhœa, 343 of soft sore, 222 of syphilis, and 44 of hereditary syphilis. The proportion of all venereal cases per 100 of the population was 1·14, and in 1898 it was 1·39 per cent. of the population.

After the abolition of the regulation in 1888 the percentage of venereal disease notified fell considerably for some years. In 1890 it was 0·90; in 1891, 0·81; in 1892, 0·99; in 1893, 1·05. After this it began again to rise In 1897, 2204 cases of gonorrhœa, 493 of soft sore, and 633 cases of syphilis, with 50 cases of inherited syphilis, were notified in Christiania, in a population of 207,000—i e, 1·65 per cent of the population was attacked by venereal contagion Dr. Boutzen, in a communication to the Brussels Congress of September last (*tome* Ir, *appendice*, p 67), *says* "Up to the year 1888 the control of prostitution was enforced in all large towns in Norway and regular examinations were enforced. When in 1888 this law was suppressed (except in Bergen and Trondhjem) I in common with most physicians entertained a fear that venereal disease would increase greatly in amount I had formerly been employed as visiting physician and, in my then opinion, that was the only means of combating venereal diseases. I was, therefore, the more surprised to find that, after all, in Christiania these diseases went on after the suppression almost as they had done before the abolition Having been one or two years after this nominated as Director of Civil Medical Services in Norway, I had to travel over all the country, and, as a general rule, I observed that the suppression of the old system had had no appreciable consequences. ...... In our country people are coming more and more to require that any measures taken against venereal diseases shall be based as far as possible on the equal treatment of both sexes, with the greatest respect for individual liberty and a minimum of arbitrary administration."

It seems to me, Sirs, that as all disseminators of preventable contagions ought to be prosecuted we might adopt with advantage the notification of cases of gonorrhœa, soft sore, and syphilis, as is done in Norway, no name being given. *Practitioners* might hand to venereal patients rules for the prevention of contagion of relatives and other persons, accompanied with warnings as to their responsibility if they should carelessly or maliciously infect any other unfortunate victim. All contracted persons, such as married people, should, if they claim it, obtain divorce from partners who damage their health in such a way. And generally speaking the law might, according to the spirit of our laws, inflict a penalty—fine or imprisonment—on any person who, carelessly or knowingly, infected another person with such a dangerous foe to life, if the victim lodged a valid complaint Such, according to M Jules Lejeune, President of the Brussels Congress and Minister of State, is as far as the State has a right to interfere in this hygienic question

I am, Sirs, yours faithfully,

CHARLES R DRYSDALE,
Consulting Physician to the Metropolitan Hospital, London.

"THE CONFERENCE AT NEWCASTLE AND THE MIDWIFERY QUESTION."

To the Editors of THE LANCET.

SIRS,—If I have somewhat laboured the question of responsibility it is because it is an important element in any scheme for midwifery nursing. It dominates Mr. Haydn Brown's scheme as sketched in his letter to THE LANCET of Jan 20th, p. 197, it is as a matter of practice essential to proper care and efficiency in work, and I am confident that medical men would for the most part be largely influenced in their estimate of any scheme by this very question; they certainly would wish to regulate their fees accordingly. Your correspondent, Mr Haydn Brown, again, in his letter in your issue of Feb. 10th, p. 420, refers to the relations between principal and assistant, and says that the obstetric nurse *could be dismissed by the medical man for malpraxis* This is hardly the point. A medical man does not wait until his assistant makes some culpable and gross mistake before dismissing him; he dismisses him if he finds that his work is not good, if it is of such a character as to keep him, the principal, in a constant *state of anxiety for fear* he should make some mistake Now I take it that it would not be possible for the obstetric practitioner to dismiss the nurse under such circumstances The question of fees is certainly a very important one, and as Mr. Hadyn Brown devotes two out of eight clauses to it I imagined that he also considered it important. Whether or not the fees are to be included in a bill does not affect their sufficiency. As to Clause 4, a casual visit by the practitioner is said to be "simply confirmative and disciplinary, to satisfy everybody. ...." I seriously doubt what such a visit would confirm; it might satisfy the nurse, but it certainly would not satisfy every medical man.

I did not suppose or suggest that all patients would be compelled to call in the obstetric practitioner, but according to the suggested scheme all who employed the obstetric nurse would have to be visited by him once at any rate and this whether they were *or not his patients* at another time. This to my mind is what would be so very likely to cause unpleasant complications between neighbouring practitioners. I did not refer to consultations between medical men, though I doubt whether in that class of patient "*consultants of standing*" would be called in as often as the neighbouring practitioner. That "women ...... need not engage the combination" is only half a truth, for if they engage the nurse they must be afterwards visited by the practitioner, and, if complications arise, be attended by him; *so that if the nurse were popular and* the practitioner not, what an unfortunate position would be created between the patient, and the obstetric surgeon, the patient and her usual medical attendant, and between the two practitioners. Mr. Haydn Brown has commenced his letter by *formulating a most flattering and comforting doctrine*, but I would remind him that silence is applicable to other things than consent and praise.

I am, Sirs, yours faithfully,

Freshford, Feb. 13th, 1900. CHARLES FLEMMING.

"MYOIDEMA IN PULMONARY TUBERCULOSIS"

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 27th, p. 230, Dr Walsham is, I think, inclined to underestimate the value *of myoidema* in phthisis. In every case where the disease is at all active, as shown by the temperature chart, I have never failed to obtain myoidema Sometimes, if there has been no loss of flesh, the small lump can be more easily felt than seen One condition is, as far as I know, peculiar to phthisis—that is, the presence of myoidema on one side of the chest only; this happens when there *is* active disease at one apex only and that slight. In cases where there is doubt whether an apex is affected or not the presence of myoidema on that *side* alone is absolutely conclusive of phthisis, though the presence of myoidema on both sides is not as conclusive. In the more advanced *cases* there is *often a* difference on the two sides as to the readiness of myoidema to appear, the more ready contraction being produced on the more diseased side. In acute cases it can often be got in every [illegible] in the [illegible]

A very fair estimate of the rate of progress of the disease at the time is given by this phenomenon; the more readily it is produced the more acute the case, and if it cannot be obtained the phthisis is quiescent.

I am, Sirs, yours faithfully,
WALTER BROADBENT, M.D. Cantab., M.R.C.P. Lond.
Brighton, February, 1900.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—Mr. Whiteford quotes one sentence from my last paragraph but he ignores the sequent and governing sentence, which runs: "But I confess, now I have got used to the Krohne inhaler and realise the significance of these deaths, that I should think it a crime to go back to a towel or a Skinner's mask." Yet this very sentence, which Mr. Whiteford passes over, has since been reprinted and made the text of an approving editorial notice by one of THE LANCET'S medical contemporaries.

Prior to this present decade no inhaler gave us greater security or convenience than the towel or the Skinner's mask. While that was so we older men were quite scientific in sticking to the open method. But that is so no longer.

Watching its effect on the pulse, respiration, and pupils is not "a method of estimating accurately the amount of chloroform absorbed." Such watchings give only a rule-of-thumb measure of the progression of the anæsthesia.

Mr. Whiteford now narrows down the "we" in his question so as to include only himself and me. This to shunt my reply. But Mr. Whiteford has forgotten that he published his question in THE LANCET of July 1st, 1899, long before I had turned up to assist him in the discussion. Is Mr. Whiteford a prophet?

I am, Sirs, yours faithfully,
JAMES EDMUNDS.
Manchester-square, W., Feb 19th, 1900.

THE DISCUSSION AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—It is of small moment to myself, but the distinguished Royal Academician Mr. Seymour Lucas may be surprised to learn that your reporter gave him credit for re-opening the adjourned discussion on Mr. Ballance's interesting paper instead of

Your humble servant,
R. CLEMENT LUCAS.
Feb 20th, 1900

PUBLIC PRESCRIBING.

To the Editors of THE LANCET.

SIRS,—We are all anxious for war news and most of us no doubt invest daily in an evening paper, but that is no reason why we should tamely submit to be insulted as a profession by the proprietors of some of these journals. When I open my paper and find one whole column devoted to the specious advertisement of an anti-gout remedy and another to the puffing of a tonic with a portrait of the "last cure" my bile rises and I am in want of one of the various liver-pills more modestly advertised in the same paper. Cannot we as a profession boycott the papers which lend themselves to this offensive practice of public prescribing?

I am, Sirs, yours faithfully,
F.R.C.S.
Feb. 20th, 1900.

THE Biennial Dinner of the Metropolitan Branch of the British Dental Association will be held on Saturday, March 3rd, at 7.15 for 7 30 P.M., at the Hotel Cecil, in the Richelieu and Medicis Rooms. Dr. Ashley Barrett, L.D.S., will be in the chair.

BATH EYE INFIRMARY.—The annual meeting of this institution was held on Feb 16th under the presidency of Alderman Bartrum. The medical report stated that 268 in-patients and 1749 out-patients had been treated. The financial statement showed that there remained a favourable balance of £31. On the motion of the Rev. B. N. Thompson it was decided that an honorarium be awarded to Mr. W. Beaumont, the honorary surgeon to the infirmary.

THE ORGANISATION OF THE PROFESSION.

GREAT YARMOUTH.—THE FRIENDLY SOCIETIES DECREE A MEDICAL LOCK-OUT.

(FROM OUR SPECIAL COMMISSIONER.)

THE medical practitioners of Great Yarmouth have successfully formed a strong union. For many years they had suffered at the hands of medical aid companies and friendly societies, but they are now energetically coping with the evil. According to the last census, Yarmouth has a population of 49,334 inhabitants; but this, of course, does not include the immense number of visitors and holiday folk who throng to this town during the sea-bathing season. The medical profession is, however, more concerned with the resident population, who belong, for the most part to the seafaring, working, and tradesman classes. There is not a large upper middle-class and wealthy residential population; still, there are the dealers in the export fish business and the import timber trade who possess some wealth. Then the season is very heavy while it lasts, so that hotel and lodging-house keepers must make some considerable profits. Of late, also, a few very good high schools have been established at Yarmouth and they have increased the residential population, as the parents of children sometimes come and live near these educational institutions. Nevertheless, even when all this is taken fully into account, it is on comparatively poor patients that the medical practitioners must rely for the greater part of their income. It is therefore very necessary that those who can afford to pay small fees should not be able to avoid doing so by joining semi-charitable institutions. There are in Yarmouth many persons who appear to be poor when they are not so. By letting lodgings in the summer months and by successful fishing expeditions considerable sums are sometimes earned. Very often these people do not live up to their income and the balance is put in a bank or devoted to the gradual purchase of a house; others, on the contrary, squander this surplus in drink. In either case it may justly be urged that those persons who in the course of a yea can earn not only enough to maintain their homes but are also able to spend in dissipation or to bank considerable sums should pay proper fees to their medical attendants. In practice, however, this is not done. Because these people are content with a low standard of living they imagine that they have a right to avail themselves of provident organisations which were originally established only for the benefit of the poor. Nevertheless, even this was to some extent tolerable so long as it applied only to the bread-winner, the head of the family. By attending the members of a benefit society for 1*d*. per week the practitioner obtained fees at the usual rate when members of his family were taken ill, and thus this contract work helped to build up a private practice. Of late, however, female lodges were founded and both women and children were brought in, so that the indirect advantage of contract work was seriously menaced.

There was no organisation capable of dealing with this grievance. Certainly Yarmouth possessed a Medico-Social Club, but it did not include all the practitioners of the district. The members met at each other's houses, read scientific papers, and then terminated the proceedings by having supper together. During the course of these social gatherings a pamphlet was circulated among the members, entitled "An Open Letter to the Profession," which urged practitioners to unite and to fight against various evils, notably against the contrac system. Mr. W. E. Wyllys spoke on the questions raised b this pamphlet, and finally it was resolved to get up a meet ing of the local profession to discuss the subject. Th meeting was held in March, 1896, in the mayor's parlour the town-hall. 19 practitioners attended, including sor who had come from the neighbouring district of Gorlesto At Yarmouth, as in many other places, there existed primary difficulty: who was to take the initiative in the mo ment? This is a delicate matter, for it does not often hap that a practitioner holds so prominent a position that can without question or cavil take the lead. The Yarmou practitioners avoided this difficulty by transferring the responsibility to an outside body. They resolved to form themselves into a branch of the Incorporated Medical Practitioners' Association. Then they applied to the central and governing body of this association, sent up their subscriptions, and received official sanction to form a branch. By thus making use of this central body they readily persuaded all the local practitioners to meet and no one was accused of taking too much on himself or of attempting to thrust himself forward. At their second gathering, which was also held in March, 1893, the medical practitioners of Yarmouth met as a branch of the Incorporated Medical Practitioners' Association and proceeded to appoint their officers—namely, a committee of five, a president, and Mr. W. E. Wyllys (25, King-street) as secretary and treasurer, a post which he retains to this day. They called themselves the Great Yarmouth District Committee of the Incorporated Medical Practitioners' Association.

Even at this early date they began to discuss the question of female Foresters. This debate was forced upon the association, perhaps somewhat prematurely, inasmuch as one of the members had resigned his position as medical officer to a female lodge of Foresters because several women who possessed good incomes had been admitted as members. The female Foresters had already applied to other practitioners to accept the vacated position, but the latter very loyally replied that they would wait till after the meeting before giving an answer. The meeting after some discussion decided that the medical officer in question had better withdraw his resignation for a period of three months so as to give the newly formed medical union the time to negotiate. From the very first the profession had displayed great unanimity, and therefore there was some hope that such negotiations might prove successful. At the first meeting 19 names were given in, but this included three practitioners from Gorleston, and as it was subsequently found that the two districts could not be worked together the Gorleston practitioners ultimately withdrew. There remained 16 Yarmouth practitioners, who, with few exceptions, included all the members of the profession in active practice. There are other medical men at Yarmouth, but for this reason or that they certainly would not take up contract work and are no longer dependent on medical practice. It may be thought that this is a very small number of medical men for so large a town, but this can be explained by the very peculiar topographical situation of Yarmouth. There are no suburbs; on the one side there is the sea and on the other side the marshes. Yarmouth is situated on a narrow tongue of land that runs from north to south. To reach any of the inland residences beyond the marshes it is necessary to go a long way round and this means a journey of some 20 miles. A town practice generally includes a certain number of country residences which, though at some distance, are accessible by a direct route, but this is not the case at Yarmouth.

The members of the District Committee met every month and one of their first acts was to draw up a letter which was addressed to all the benefit societies urging that a joint conference should be held so as to discuss the existing grievances. The terms on which the medical practitioners were willing to take up contract work were also fixed and these were printed and sent round to all the clubs. In reply, the benefit societies adopted a lofty tone and the majority refused to entertain the proposals made by the medical practitioners. Two benefit societies did, however, accept the new rules and conceded to their medical officer the right to refuse those members whom he thought were too well off to belong to such societies. They also agreed to an increase in the amount to be paid as subscriptions. The other benefit societies adopted a course which was singularly devoid of tact and showed that they in no wise appreciated the situation. They held a large meeting at which the following resolution was adopted :—

> This representative meeting requests the doctors to withdraw their circular and retain their position on the old terms and take females on the same terms as the males.

The medical men were further called upon not to raise the question in future. In a word, there was to be no improvement, and the medical officers were to pledge themselves never in future to seek to obtain any such ameliorations. This resolution was passed in October, 1896, and the medical officers at once replied that they adhered to their former demands; at the same time they decided that they would not resign but that they would wait to be dismissed. The benefit societies had put themselves in an awkward position, for they had called upon their medical officers to pledge themselves not to raise these questions in the future. Of course, they all very naturally refused thus to pledge themselves, and this demand being rejected the benefit societies thought themselves bound to dismiss their medical officers. Thus the onus of dismissal fell upon the benefit societies; it was not a strike but a lock-out.

At the time when matters had come to a head the Yarmouth practitioners addressed a memorial to all the medical licensing bodies of the United Kingdom calling attention to the evils and abuses of the clubs and medical aid societies, and expressing the desire that these licensing bodies should give their opinion on the conduct of those of their graduates and holders of diplomas who by accepting appointments in such institutions aided and abetted in the perpetration of the abuses in question. This memorial set forth that well-to-do persons were admitted to institutions which were meant primarily for the relief of the poorer classes; that women and children were admitted at rates of payment that were absolutely inadequate; and that industrial assurance companies had organised a system of indiscriminate canvassing whereby the private patients of other medical men were solicited directly for the company and indirectly for its medical officers. These lay organisations conducted medical practice purely as a commercial speculation, in some cases paying their medical officer a fixed salary and appropriating for themselves whatever medical fees were received over and above this sum. At Yarmouth these societies had refused to come to an understanding with their medical officers and had dismissed them. They then advertised in the lay press for other medical men to take up this work, the medical journals having refused to insert such advertisements. Though fairly warned that such conduct was condemned by the general voice of the profession, some medical men had accepted these appointments thus "knowingly, wilfully, and openly assuming the position of assisting a certain section of the public to defeat the local medical men in a matter involving the vital interests of the profession." The memorial to the licensing bodies then went on to relate that .—

> One of our members had previously acted as the medical officer of an industrial assurance company offering medical aid as an attraction to its insurers, paying its medical officer a fixed salary and canvassing for patients from door to door. This office he has resigned, but in the absence of any declaration as to these appointments by the General Medical Council or by the universities and colleges granting medical qualifications the company has, we believe, easily found a substitute. Such facts as we have recited can be quite paralleled in the experience of other towns and districts of the United Kingdom and appear to us to call for the careful attention of the various governing bodies entrusted with the granting of medical qualifications and with the control of those qualified.

The memorialists concluded by inquiring whether the holding of such positions was compatible with the degree or diploma granted, and if it did not contravene existing regulations, would it not be possible to enact a new by-law forbidding such practice? And was it not desirable that the General Medical Council should declare such conduct to be infamous from a professional point of view? This memorial was signed by 15 of the Yarmouth practitioners; and it is worth noting that though it often happens that Irish medical men are the offenders in regard to such club practice, the most sympathetic and encouraging replies were received from the Irish licensing bodies

Great Yarmouth.

(*To be continued.*)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Health of the City.

THE report of the medical officer of health, Dr. A. Hill, for 1899 has been issued by the Health Committee. It contains much useful and valuable information. The birth-rate for the year was 34 3, a higher figure than in any year since 1885. The death-rate was 20 5 per 1000; this is an increase over the average and is due to mortality from diarrhœa and enteritis during the hot months. The zymotic death-rate was small, being 2 9 per 1000. No case of small-pox has occurred for three years past. Typhoid fever shows an increase owing to a severe outbreak in the autumn, the number of deaths being 119, or 20 more than the average. Dr. Hill expresses his strong conviction with regard to the infectiousness of this disease—that direct contact with the person or belongings of a typhoid fever patient is one of the greatest factors in the spread of the disease. Some interesting details are given in reference to the diagnosis and treatment of diphtheria. Under the arrangement made with Mason University College 269 specimens from the throats of persons who had some symptoms of diphtheria were examined. In 123 instances the characteristic bacillus of diphtheria was found. Antitoxin was supplied to 108 cases where the bacillus was found and to 10 cases in which it could not be discovered; also in 94 cases where no examination was desired. The report says that in addition to defraying the cost of primary examinations the committee here also decided to pay the cost of examinations at the College which medical men may desire to have made before certifying the complete recovery and freedom of patients from the disease. The women health visitors appointed last April have done useful work; they visited about 11,700 houses and paid about 3000 revisits. Altogether evidence is given of the activity and value of the Health Committee's labours.

Birmingham and the Medical Arrangements for the War.

Mr. J. F. Hall-Edwards, surgical radiographer to the General Hospital, has been appointed x ray expert and surgical photographer to the Hospital of the Imperial Yeomanry at Cape Town. Messrs. Parker and Sons, electrical engineers, of Wolverhampton, have made a gift of a dynamo for electrically lighting the operating theatre of the Imperial Yeomanry Hospital. It will serve also to furnish the current for the x ray work. Mr. Hall-Edwards is to take this with him as well as photographic apparatus of all kinds voluntarily supplied by the public for his use. The city has also supplied ten members from the St. John Ambulance Brigade, whose appearance elicited pleasing comments from the commissioner. On Feb. 12th an urgent telegram for ten more men was received. In spite of the short notice more than the original number had volunteered by the next morning from the ranks of the police and civilian members of the local branch, promptitude which speaks well for the organisation.

The Workhouse Infirmary.

The Workhouse Infirmary of Birmingham holds a high reputation among similar institutions, being said to be one of the finest and best equipped in the country. On Feb. 2nd the Lord Mayor (Alderman Beale) and the Lady Mayoress paid a lengthened visit to the wards, thoroughly examining the whole building. The Lord Mayor expressed himself as having for the first time realised the importance of the duties discharged by the guardians. As to the infirmary, he stated that the excellent arrangements and management entirely justify the high reputation in which the infirmary is held.

Feb. 20th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary.

AT the annual meeting of the trustees of the Manchester Royal Infirmary which was held a few days ago the chairman, Mr. Edward Heywood, moved the adoption of the report and mentioned the negotiations which had taken place with the corporation respecting the sale of the infirmary site. The infirmary board named the sum of £400,000 for submission to the trustees, but as the city council decided not to offer that sum the negotiations came to an end. He also moved:

> That the trustees hereby authorise the board of management to appoint a committee to deal with the last resolution of the medical board as given in the annual report with a view to ascertain (1) whether or not a hospital suitable in every way can be built on a plan other than the pavilion; and (2) if this be decided in the affirmative by such committee, that the board of management be authorised to take steps to obtain suitable plans and estimates and to incur all necessary expenses in connexion therewith.

He believed that the best thing for Manchester would be to have a great central hospital on the site where the infirmary has stood for nearly 150 years. Dr. T. Harris seconded the resolution and said that the advance of science rendered it doubtful whether a pavilion hospital at the present time was an absolute necessity. Dr. D. J. Leech said that the first part of the resolution commended itself to all the trustees, but he felt some doubt about the second part. The pavilion type of hospital had been considered necessary for 20 or 30 years and was still held to be the best. Mr. G. A. Wright supported the resolution, which was carried almost unanimously. It would be useless to speculate as to the future. Should the corporation take heart and offer a sum sufficient to make it worth while for the infirmary to sell the whole site it would provide for the building of a large and fully-equipped hospital on another site and secure a worthy position for the Art Gallery and Free Library, which is one of the needs of Manchester. It is also by no means certain that the present site of the infirmary is sufficiently large for the great hospital with its administrative buildings which is deemed necessary for Manchester, even if some type inferior for hospital purposes to the most approved be chosen.

Manchester and Salford Sanitary Association.

The annual meeting of the Manchester and Salford Sanitary Association was held last week, Mr. T. O. Horsfall, in the absence of Dr. Leech, being in the chair. The chairman regretted the lack of interest shown by the people of Manchester in the association, which was indicated by the small amount of the subscriptions (£164 14*s*.) received during the past year. He mentioned one instance showing the pressing need for improved physical education. Out of 11,000 young men who had presented themselves as recruits from Manchester only 3000 could be accepted, and of the latter only 1000 were found fit to serve in line regiments. Against a great town like Manchester, he thought, "no more disgraceful fact had been recorded in human history." If the like holds good of the other great towns of our country the prospect of our being fit to meet possible international difficulties is but poor. Without touching on politics, the situation must be spoken of as perilous, and it is the duty of all, and especially of those who have the control of our educational schemes, to see to it that our boys have a fair chance of possessing sound and healthy bodies, and minds filled with something more practically useful than the mere mass of ill-digested book lore which seems to be too often the outcome of our present-day methods.

Hospital Sunday.

The dreadful weather of Sunday, Feb. 11th, had the effect of so reducing the Machester congregations that the Hospital Sunday collections were grievously lessened. Indeed, in some cases the congregations were so poor that it was decided to postpone the appeal for the hospitals. That at the morning service at the Cathedral numbered, exclusively of clergy, choir, and the boys of the Cheetham Hospital, which is close by, only 40 persons, although it is usually crowded. "The committee of the Hospital Sunday and Saturday Fund appeal to all to support in their various places of worship any arrangement that may be adopted for furthering the interests of the medical charities of Manchester by generous contributions." The sum collected has of late rather fallen off, and this year with the pressing claims of those who are dependent upon our soldiers many charities will suffer. It is said, however, that just now Manchester is exceptionally prosperous and will therefore still be able to give freely. Many have long felt that a more genial time of the year should be chosen for this annual effort. The heavy snowstorm of Feb. 11th is a strong argument in favour of a change of date which should surely be made. If this is agreed upon the collection should be fixed for a day either before or after the summer holiday season, or the results will be disappointing. Obviously it would be best to have the collections before the holiday season has begun.

Feb. 20th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Liverpool Royal Infirmary.

THE report of the Liverpool Royal Infirmary states that the number of in-patients during the year 1899 was 3012, with an average residence of 27·95 days. There had been 23,605 attendances of out-patients, and 58,883 re-dressings, so that altogether they had dealt with 82,488 cases during the year. The receipts were £13,452, and the expenditure was £14,129, leaving a deficit of £1269.

The increased prosperity of the country had not benefited the institution in the matter of extra donations The contribution from the Hospital Saturday and Sunday Fund was £2783 or an addition of £190 for the year The question of rating had been a source of trouble to the committee While formerly they paid no rates, since 1893 they had paid poor rates on £510 assessment, which was, however, a liberal reduction of their assessment Representatives of 39 charities in Liverpool had asked the finance committee of the city council to relieve them from the city rate, but without a satisfactory result, owing to the present state of the law The consequence was that the Royal Infirmary had to pay poor and city rates amounting to 6s 8½d on the assessment or a sum of £163 per annum The town of Derby had obtained a local Act relieving medical and other charities from the payment of rates, and it was hoped that it might be possible for the Liverpool Corporation to introduce a clause in their omnibus Bill freeing Liverpool charities from the payments of rates which were considered to be a great hardship upon all charitable institutions Mr Charles Langton was elected president for the ensuing year, and Mr Edward Hewley was elected chairman of the committee

The Liverpool Royal Southern Hospital

At the annual meeting of the Liverpool Royal Southern Hospital, held on Feb 12th, the treasurer announced that owing to extensive improvements effected during the year the hospital was in debt to the extent of £4000 The Lord Mayor said that about £50 000 would place all the Liverpool charities in a condition of comfort, and he thought that it was a pity that Liverpool merchants some of whom he had heard, had made from £50 000 to £200 000 out of the war, did not give more to these charities

The Municipal Bacteriologist

Professor R W Boyce of University College has been appointed municipal bacteriologist at a salary of £600 a year

The Stanley Hospital

The new out patient wing which has been added to the Stanley Hospital at a cost of £2000 by the trustees of the Roger Lyon Jones Trust will be formally opened on Feb 22nd by the Lord Mayor The wing is placed at the rear of the institution and is connected with the main building by a covered way It contains a large and well ventilated waiting room, heated by hot air pipes and is capable of accommodating 200 patients There are also a porter s lodge, consulting rooms for the physicians and surgeons a dispensary, and other necessary accompaniments The hospital will provide 20 beds for the disabled soldiers arriving from the seat of war

The Liverpool Medical Institution and the Prevention of Tuberculosis Presentation to the Sub Librarian

The following resolution was carried unanimously at the recent meeting of the society on the proposition of Dr Nathan Raw —

> That it is desirable that a local branch should be established in Liverpool in connexion with the National Association for the Prevention of Consumption and other Forms of Tuberculosis

A sub committee of the institution was appointed to carry out this object —Mr. William Jones the resident librarian of the Medical Institution at the same meeting was presented with a cheque for £193 12s 9d, subscribed by the members in appreciation of his valuable services during a period of 21 years Mr Jones acknowledged the gift in a humorous and happy reply

The Proposed Parochial Hospital for the Treatment of Tuberculosis

At a meeting of the select vestry held on Feb 6th, a letter was read from the Local Government Board enclosing the draft of an Order which the Board had caused to be prepared for combining the unions of West Derby, Liverpool, and Toxteth, for the purpose of providing a joint hospital for paupers suffering from tuberculosis The document consisted of 86 sections which several members of the vestry pointed out, a lawyer would have to decipher The consideration of the communication from the Local Government Board was adjourned for a fortnight to enable the vestry clerk to prepare for the members an abstract of the document setting forth its meaning The matter will be fully discussed at the next meeting of the select vestry

Extension of a Corporation Infectious Hospital

Plans were submitted to the health committee for the enlargement of the administrative block, the erection of a porter s lodge and a patients' discharge block at the Corporation Infectious Hospital, Linacre, at an estimated cost of £2050 The necessity for an immediate provision of additional sleeping accommodation for the nursing staff was found to be pressing During the past few years there had been an overcrowding of the staff through lack of sufficient room, giving rise to much inconvenience The out districts supplying patients to the hospital—viz , Waterloo, Seaforth, Sutherland and Great Crosby —would be called upon to contribute to the expense incurred The plans were approved and tenders for carrying the work into execution were issued

The Outbreak of Ophthalmia at the Liverpool Workhouse

Dr W Alexander surgeon to the workhouse hospital, has reported the prevalence of ophthalmia amongst children under the care of the select vestry He instanced the satisfactory results obtained from isolation and treatment of the children at Olive Mount and Maghull. Successful treatment was impossible in the workhouse itself, and he urged the retention of the children at those two institutions The ignorance of parents had had a great deal to do with the spread of the disease Parents should be encouraged to leave their children in the workhouse until a cure was effected If treatment could not be conducted in the future at Olive Mount or Maghull, he suggested the establishment of an ophthalmic school for 40 children—20 boys and 20 girls—at some suitable place The terrible scourge could only be stamped out by isolation and rigorous treatment A bacteriological and pathological report of the ophthalmic cases had been obtained by Dr Alexander from the Thompson Yates Laboratories This was described by Mr William Rathbone as an extremely valuable document which should be printed and circulated amongst the members of the select vestry, and copies he said should be sent to other boards of guardians

University College, Liverpool, and the Royal Army Medical Corps

The Secretary of State for War has offered the authorities of University College a nomination for a commission in the Royal Army Medical Corps for a student of the College Candidates must be duly qualified and physically fit After undergoing the usual physical examination and being approved by the Director General of the Army Medical Department the nominated candidate will be required to report himself at Netley on March 1st to undergo the necessary course of instruction

Feb 20th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Suicide in Scotland

AT a meeting of the Royal Society of Edinburgh on Feb 19th Sir John Sibbald delivered an address on the Statistics of Suicide in Scotland He said that the information to be found on that subject in the Reports of the Registrar General had not been as in other European countries digested and tabulated He then presented a series of statistical statements which he had prepared and in which he had collected and arranged this information The tables showed (1) the influence of age and sex on suicide, (2) the comparative frequency with which different methods were employed, (3) the influence of the time of year on the number of suicides, (4) the influences of town life and country life respectively, and (5) how far they were justified by a study of these statistics in accepting the assertion that in Scotland as in other countries suicide was on the increase The statistics for Scotland showed the same preponderance in the number of suicides in summer over those occurring in winter as had been shown by the statistics of every country in which the matter had been investigated The suicide rate gradually rose from the months of November, December, and January to the months of May, June and July after which it gradually fell This he considered to be one of the most remarkable facts in vital statistics the proportional progress from month to month being almost identical for all countries north of the equator, As regards the question of town and country life the statistics of Scotland did not support the statement that suicide was more frequent in towns. The suicide-rate in the mainland rural districts was somewhat higher than the rate in the large towns. The counties along the east coast of Scotland had higher rates than those along the west coast from the Mull of Galloway to Cape Wrath. The average rate for the whole of Scotland during the 18 years from 1877 to 1894 was 55 per 1,000,000 of population. The lowest rates were for the Highland counties lying north-west of a line drawn from the Moray Firth to the Firth of Clyde. The highest rates were shown by Kincardine, Forfar, Mid-Lothian, Linlithgow, and Haddington, all of which had rates over 71. These facts were illustrated by means of a coloured map. The Registrar-General's returns for successive years showed a great increase in the number of suicides. In spite of this, however, Sir John Sibbald did not believe that they were justified in accepting the increase as a fact. It had to be borne in mind that of late years public opinion with regard to suicide had altered considerably. It was now so universally recognised that in the greater proportion of cases suicide was the outcome of mental disease, that the idea of disgrace was not so closely connected with the act, and efforts to conceal its occurrence had consequently decreased. Another point which had also to be taken into account was the greater efficiency during recent years of the administrative machinery for registration. After considering the rates for the different methods of suicide Sir John Sibbald concluded by saying that it seemed clear that the alleged increase of insanity must be regarded as not proven.—Dr. Clouston congratulated Sir John Sibbald on the valuable addition he had made to vital statistics. In the course of a few remarks he said that as regarded the medical aspect of the subject, between two-thirds and three-fourths of all cases of melancholia either felt suicidal or attempted suicide, but that there was also no doubt that excess of alcohol produced a condition of brain which frequently led to suicide, and that if there was an increase of suicide it was not due to the intensity and difficulty of living but to the excessive use of alcohol in our cities. He believed that the fact that suicides were more frequent at certain seasons was due to a reversion to the old sexual conditions of the ancient ancestors of the human race. As regarded the distribution of suicides there was no question that the Celt with his vivid imagination, though often melancholic, feared death more than the Teuton did.

The Dietary and Food-Supply of the Poor in Edinburgh.

At a meeting of the Edinburgh Town Council on Feb. 13th a letter was read from Dr. Noel Paton, superintendent of the Research Laboratory of the Royal College of Physicians of Edinburgh, asking the interest of the Town Council in a study upon which he was engaged of the dietary and food-supply of the poorest classes. The object of the study was to obtain data which should serve as guides in directing the poor how to obtain satisfactory food-supply at the lowest cost. He further asked the Town Council for a sum of £50 in order to enable a preliminary study to be made. Enclosed with the letter was a statement describing the method of procedure in this study. It is being carried out in the Research Laboratory of the College of Physicians with the coöperation of Dr. J. C. Dunlop in the scientific part of the work and of Dr. S. Inglis and a staff of voluntary workers in the collection of materials and information. The letter was sent to the Public Health Committee of the Town Council for report.

Feb. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Victoria Eye and Ear Hospital, Dublin.

AT the annual meeting of the supporters of the Royal Victoria Eye and Ear Hospital, Dublin, held at the Mansion House on Feb. 13th, the honorary secretary (Mr. Henry R. Swanzy) was enabled to make the important announcement that the council had succeeded in purchasing a desirable site in Adelaide-road for the long-contemplated new buildings. The plot is situated on high ground and has never yet been built upon. It is large enough to accommodate a corridor hospital with 120 beds, besides apartments for the staff of nurses and a separate building for the treatment of extern patients.

Death of Samuel George Wilmot, M.D. Aberd., F.R.C.S. Irel.

Mr. Samuel George Wilmot, Ex-President of the Royal College of Surgeons in Ireland, died at his residence, 4, Vesey-place, Kingstown, on Feb. 17th. A circular has been issued by the President requesting the Council and Fellows of the College to attend his funeral which will leave the Royal College of Surgeons on the morning of Feb. 21st for the cemetery at Mount Jerome. Mr. Wilmot, who had retired from the practice of his profession for some years, was formerly well known and highly esteemed in Dublin. He was for a long period surgeon to Steevens' Hospital and consulting surgeon to the Coombe Lying-in Hospital.

The Ulster Medical Society.

On Feb. 16th Alderman James Graham, M.D. (chairman of the Public Health Committee of the City of Belfast), in his official capacity as President of the Ulster Medical Society, entertained the members of the medical profession and his municipal colleagues in the Exhibition Hall, Belfast, which was comfortably warmed and beautifully furnished and decorated for the occasion. The entertainment took the form of a smoking concert. Mr. Boyle's string band was present, and a most enjoyable concert was provided, while, in addition to the music, Dr. J. S. Morrow and Dr. A. Fullerton gave recitations. An interesting kinematograph exhibition was also shown. Supper was served in the ante-room. The evening was a most enjoyable one and the entertainment was characterised by that cordial hospitality for which Dr. Graham is proverbial. Such occasions do much to cement that feeling of brotherhood which is so important to the medical profession.

Extra Professional Assistance in Dispensary Cases.

The Local Government Board have written to the Limavady guardians stating that in their opinion, both in the interests of the ratepayers as well as of the sick poor, reasonable remuneration should be fixed for extra medical assistance, and urging them to adopt a scale, as otherwise, in the case of legal proceedings, they might be obliged to pay very much larger fees than those suggested by the medical officers. At their meeting on Feb. 19th the Limavady guardians adopted a scale of one guinea with one shilling mileage on the outgoing journey for daytime, and a guinea and a half with similar mileage for night. It is hoped that the Local Government Board will decline to accept such a low rate of payment.

Londonderry County Infirmary.

Under the new Local Government Board the committee of management is to be constituted of 11 of the old governors (who were elected on Feb. 13th), a like number of the City of Derry Corporation, and four to be selected by the Derry County Council. The Local Government Board, by the advice of the adjuster of taxation, has assessed the city corporation at £1250 a year for the maintenance of the infirmary and the county at large at only £244, which the city authorities regard as inequitable. The county council are to be asked to summon a special meeting to elect their representatives, as until this is done the new board of the infirmary cannot be constituted.

Appointment to the Chair of Surgery at the Queen's College, Cork.

Dr. C. Yelverton Pearson, Professor of Materia Medica at the Queen's College, Cork, has been appointed to the chair of Surgery, rendered vacant by the death of the late Professor Stephen O'Sullivan. Professor Pearson is surgeon to the Cork North Infirmary and has had considerable experience as a clinical teacher. The chair of Materia Medica is now vacant and already several candidates are in the field.

The Nursing Question in the Belfast Royal Victoria Hospital.

For a considerable period there has been friction between the authorities of the Nurses' Home, Belfast, and the Royal Victoria Hospital in reference to the payment of nurses and the question has reached an acute stage owing to the fact that the committee of the Nurses' Home have intimated to the board of management of the hospital that their financial position is so critical that they can no longer supply special nurses to the hospital except at the ordinary market rate of 25s. per week and board and lodging, and that they will put on no new probationers to replace those completing their time until some satisfactory arrangement has been concluded with the hospital. The whole question has been referred to the Finance Committee of the Royal Victoria Hospital and some of the medical staff, who are to meet a sub-committee of the Nurses' Home and try to arrange a *modus vivendi.*

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Difficulties in making Post-mortem Examinations in Hospitals

DR NAPIAS, the head of the Assistance Publique, has sent a most disturbing circular to the authorities of all the hospitals, one which, moreover, has called forth the most lively protestations from the heads of the various hospital departments. Under the pretence of sticking strictly to the letter of certain ancient enactments dated Dec. 3rd, 1834, and which formally forbid the practice of dissections in hospitals, the head of the Assistance Publique recalls the fact that the only object of a post-mortem examination should be simply to ascertain the cause of death Any mutilation or removal of any organ—however interesting it may be from a pathological or other scientific point of view—is therefore forbidden on principle. In future, then, no pathologist must remove or preserve any organs or portions of organs without having made a special request to Dr. Napias stating in detail the reasons for his action and the scientific interest of the specimen. Dr. Napias has decided that henceforward this permission will only be very exceptionally granted. As a reason for this stringency he gives in the case of bodies which are claimed the necessity for safeguarding the rights of the relatives, and in the case of unclaimed bodies the necessity for handing over to students of anatomy subjects which are complete and possess all the viscera, whereas at present bodies are sent from the hospitals with the thorax, the abdomen, and the skull quite empty. As Dr. de Maurans says in a sensible article in the *Semaine Médicale*, this circular not only runs counter to the scientific interests of medicine, but also to those of the sick. Clinical medicine can nowadays make no serious progress unless it goes along with accurate anatomico-pathological research. It is to be hoped that this regulation, which creates for the medical profession of Paris a situation so harmful and at the same time places them in a position differing from that of the profession in every other country, will, like so many other official regulations in this country, remain a dead letter.

Rates for Gratuitous Medical Attendance.

Once more there is a great discussion over the application of the enactment of July 15th, 1893, which dealt with the question of gratuitous medical attendance for the poor. It made it compulsory upon every commune and department to allocate from their funds a sufficient sum to provide for their poor obtaining medical attendance, and, further, should the gravity of the case demand it, removal to the nearest hospital which was in future bound to take the case in. The State takes cognisance of the matter with regard to the amount of the rating, which of course varied with the rateable value of the district and the number of poor. Owing to the great latitude left to the local bodies (*conseils généraux*)[1] to vote the annual sums necessary the enactment has been applied very differently in different districts. To-day, seven years after the passing of the Act, there are some departments where it has never been put in force. True, in the great majority of places the system is well organised and in good working order; in others, as Lot-et-Garonne, Alpes Maritimes, Gard, the Landes, and Hautes Pyrénées, the organisation is rudimentary; in others, still it is better, but only works with difficulty. The crux of the whole matter is deciding how much the medical man shall be paid Generally, the sum depends upon the number of visits paid, a small sum being added for mileage. Although the fees are anything but high medical men are generally content because there is a fair relation between the amount of work and the pay. But a dispute has arisen in the department of Ille-et-Vilaine owing to the local authority claiming the right to pay the medical man a definite sum for every patient on the list, however many visits may be necessary. This sum is fixed at 1 franc per annum or 1 franc 50 cents if medicines are provided. If it be calculated that a third of the poor on the list will send for the medical officer during the year, and that these patients for the most part will be laid up for varying lengths of time necessitating a certain number of visits, it is obvious how absurd is the rate at which the local authority wishes to pay the medical man. The syndicate of medical men in Ille-et-Vilaine have refused to agree to these conditions, so the matter is still in debate, and the poor are without medical attendance until the Minister of the Interior shall decide the point at issue. What is remarkable is that all the neighbouring departments have adopted the system of payment by visit and have found it work most satisfactorily.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch on Malaria.

PROFESSOR KOCH'S report of his expedition to the Dutch Indies for the study of malaria has been published by the medical department of the Colonial Office in a recent number of the *Deutsche Medicinische Wochenschrift.* He commences by stating that malaria has decreased considerably not only in Batavia but also in the other towns of the colony, so that during five weeks only 30 cases of malaria in an active stage could be examined; the other cases under observation were either convalescents or suffering only from sequelæ of the disease. In the colonial army the number of patients had decreased 60 per cent. during the last 15 years, a fact partly due to hygienic improvements but especially to the systematic treatment of malaria by quinine. In Professor Koch's opinion the distribution of quinine to the population free of charge is a very judicious measure. During the last 10 years on an average 2000 kilogrammes (39 cwt.) of quinine were distributed every year and Professor Koch advised the governments of countries where malaria is prevalent to follow the example of the Dutch authorities. He then discussed the question whether malaria is communicable to animals or not. He injected blood of malaria patients into monkeys (orang outangs and others) but no malaria was produced; he therefore concluded that malaria was confined to the human subject. From Batavia the commission proceeded to Ambarawa in the hope of finding there a more ample supply of material for research; but although Ambarawa is situated in a marshy region only a small number of recent cases of malaria were found. Professor Koch was of opinion that the general population having contracted the disease during the period of youth had become immune against it. To test this hypothesis he examined the blood of children and detected the parasite of malaria in about 9·2 per cent.; in another village the proportion was even 22·8 per cent. From Ambarawa the commissioners went to Tosari, having received the information that this was the only place in Java where malaria occurred apart from mosquitoes. They found there one malaria patient who, however, had caught the disease elsewhere; no parasites were to be seen in the blood of children. The researches conducted in Java have therefore confirmed the view that endemic malaria exists only in places where mosquitoes are to be found. Professor Koch believes that malaria is less malignant in Java than in Africa; in the former country the real tropical fever was present in only 47 per cent., whilst in East Africa 89 per cent. of the patients suffered from the malignant form Professor Koch finally insists upon the necessity of examining the blood of children in places where the adult population is free from malaria, for it is only in this way that a reliable result can be obtained. The commission will proceed from the Dutch Indies to New Guinea.

Public Health in South Africa.

In the Berlin Societ

---

[1] There is no institution in the British Islands which answers exactly to a conseil général, but perhaps a county council has to perform nearly the same functions

read a paper on the Hygienic Conditions of South Africa from the Cape to the Zambesi River. He is particularly well informed on this question, having visited those countries, together with Professor Koch, for the purpose of studying rinderpest. He said that the climatic conditions of South Africa are not yet thoroughly investigated, the number of meteorological stations being relatively small. The public health service is well organised. There are public health officers whose duties include travelling over their respective districts and using the necessary means in the event of outbreaks of infectious disease. Bacteriological institutions, good hospitals, and leper asylums exist, and the notification of infectious diseases is strictly enforced. A large portion of South Africa is very healthy and would be very suitable for phthisical patients if trees were more plentiful. Water, however, is very scarce, so that the rain water has to be collected and stored in reservoirs, and better methods of filtration are required. Among endemic diseases enteric fever claims the first place. This disease is of a severer type in Africa than in Europe owing to a greater virulence of the bacilli. South African practitioners are of opinion that this aggravation of the symptoms is due to a combination with malaria. The British troops would probably suffer from enteric fever to a greater extent than the Boers would, the majority of the latter having had the disease in childhood and being therefore protected against it. Some of the British regiments have been inoculated with anti-typhoid serum and some have not, and Professor Kolle remarked that it will be of great interest to observe the differences, if any, in the attack and in the degree of malignancy in the two classes. Malaria is prevalent in many districts of South Africa, and certain species of mosquitoes are capable of conveying the germs of the disease. Finality has, however, not yet been reached in our knowledge of the relations between mosquitoes and malaria. The endemic dysentery of South Africa is comparatively mild. The grave form of dysentery affecting the British force was probably conveyed by troops coming from India. Scurvy also occurs in South Africa owing to the deficiency of fresh vegetables. Bubonic plague has never been prevalent there, in the author's opinion, because there are no rats. Small-pox is widely spread, but the medical authorities have now succeeded in preparing vaccine lymph in the country. Tuberculosis is very little known in South Africa, whereas, on the other hand, leprosy threatens to become in course of time a real danger for the population. In conclusion, Professor Kolle gave an account of the rinderpest and the immunisation of cattle performed by Professor Koch, by himself, and by Dr. Turner.

A University for Hamburg.

Rumours are current that the municipal authorities of Hamburg intend to establish a university. This large commercial city, one of the confederated states of the empire, possesses many scientific institutions, partly belonging to the city and partly supported by the liberality of the wealthy inhabitants. One of these is an ethnological museum, very rich in interesting specimens, the collection of which has been facilitated by the free communication between distant countries and this great seaport, the largest on the continent. There are also a museum of antiquities, a museum of arts, an observatory, a chemical and a physical State laboratory, an institution for natural history, a botanical institute, and a great public library. With respect to medical science there are a number of good hospitals, of which the new State hospital at Eppendorf is the largest; it is also one of the best equipped on the continent. The Institution for Tropical Diseases established by the Imperial Government will be in connexion with the hospitals of Hamburg Representatives of the above-mentioned institutions have occasionally delivered popular lectures in Hamburg, but there has not hitherto been any systematic course of study. As a first step in the direction of university organisation the Senate of Hamburg has submitted a Bill to the representative assembly of the city providing that the heads of the above institutions, together with a staff of lecturers, shall form the "teaching body" of Hamburg and shall be entitled to elect a rector. The number of lectures will be augmented, and it is hoped that the combination of the individual scientific institutions may lead in course of time to the formation of a fully-equipped university to which students may be admitted.

Feb. 19th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Apparent Death and Premature Burial.

SHORTLY after the great cholera visitation of 1866 Dr. Filippo Pacini, professor of anatomy in Florence (who gave his name to the "corpuscula nervosa"), called attention to this subject in a memorable paper. He cited not a few cases in which the patient, certified as dead, had come to life on his way to the cemetery, and he started the not unnatural—if horrible—inference that the resuscitation referred to may in several instances have come about within the grave itself. The rapidity, not to say the haste, with which burial follows death in Italy gave colour to the gruesome surmise. Indeed, the next great cholera epidemic—that of 1884—afforded something very like a case in point. At Turin a well-known physician who had lived through the epidemic was at last seized with the malady and, worn out by professional duty, failed to rally. Certified as dead, he was laid out for the offices of the undertaker in a room adjoining that in which his wife and family were awaiting his consignment to the coffin. To their horror and amazement he appeared at the door in his winding-sheet, and, in a voice barely audible, reproached them for having left him so long uncared for. Every effort was immediately made to ensure his rescue, but in vain: He relapsed, and death, real this time, not "apparent," supervened. Had the undertaker arrived 20 minutes sooner the unfortunate man would have revived under the coffin lid. The incident made a profound impression at the time and restarted, while redoubling, the apprehensions aroused by Pacini. Now we are having another such recrudesence of these, the heavy mortality due to influenza and the all too brief interval between the issue of the death certificate and the interment or cremation of the victim sufficing to re-awake them. Unfortunately for the peace of mind of the public a highly sensational, but quite authentic, case of the kind—not, however, occurring after influenza—is reported from Southern Italy. At Lecce a young country woman, as the result of a very difficult confinement necessitating much unavoidable intervention, appeared to have died, her offspring, also given up for dead, remaining in utero. In accordance with Italian custom the funeral was fixed for the next day and the body was left in its coffin in the mortuary chapel adjoining the cemetery. Early in the morning, some hours before the burial, a photographer who was commissioned to take the poor woman's likeness obtained leave from the *custode* of the chapel to open the coffin. Hardly was this done when the two men were shocked to find that the corpse, which had been placed on its back, was now on its side and close to it was a lovely child wanting both arms, which had been detached during the obstetric operations. The judicial authorities, including the "giudice istruttore," were at once called in and found that the woman had come out of the lethargic condition in which she had appeared as dead and had given birth to her child in the coffin—"dop atroce agonia," says their report, resulting in the suffocatio of both. It seems from evidence extracted from the *custod* that during the night while a storm was raging he had hear feeble cries as of some one calling for help in the mortua chapel. The tragedy, for such it is, has evoked much co ment, pending the official inquiry now in progress.

The English-speaking Practitioner in Italy.

A Cabinet Council has just been held for the purpose examining the Bill shortly to be introduced into Parliament for regulating the practice of their profession by foreign medical men in Italy. "Our laws," says the official report communicated to me, "allow such medical men to practise among their compatriots resident in the country; but to secure their confining their practice within these limits is very difficult, for it is found that they not only encroach on the *clientèles* of other nationalities, but even on the *clientèle* exclusively Italian. The medical men of Italy, therefore, crave of the Government to obtain for them reciprocal rights, that is, to get them entitled to practise abroad, without their being obliged, as at present, to undergo a fresh examination in the language of the country where they wish to practise. Foreign Governments," continues the report, "refuse this reciprocity. Hence our Government in self-defence, while wishing to interpret professional liberty in the most liberal spirit, will have to insist on an examination in Italian to be undergone by these foreign practitioners who practise in Italy." It is not said whether the contemplated legislation is to be retrospective and whether the English-speaking practitioner, for instance, who has long been settled in Italy will virtually have to qualify anew by taking an Italian degree. Be this as it may, the object of the Bill is clearly to exclude the foreign, particularly the British or American, practitioner and to open to Italian medical men the lucrative *clientèle* hitherto enjoyed by graduates from the British Isles or the United States.

An Anti-Vivisection Bill Introduced in the United States.

READERS of THE LANCET may have read that an anti-vivisection Bill has recently been introduced into the United States Senate by Senator Gallinger, the measure having for its nominal object the prevention of cruelty to animals in the District of Columbia. The District of Columbia has twice favourably reported on the Bill so that it would appear that *this ill advised action on the part of the Senator may have the* effect of very considerably curtailing the scope of scientific research in that portion of the United States. Dr. W. W. Keen of Philadelphia, the President for this year of the American Medical Association, refers to the matter in these well-chosen words: "The Bill is speciously drawn up as if it were intended only in the interest of prevention of cruelty to animals. The real object of the Bill is twofold—first to prohibit vivisection and secondly to aid the passage of similar Bills in all the State legislatures. I need hardly point out that this would seriously interfere with or even absolutely stop the experimental work of the Bureau of Animal Industry and of the three medical departments of the Government—the army, the navy, and the marine hospital service. The animals themselves *might* well cry out to be saved from their friends. No more humane work can be done than to discover the means of the *prevention of diseases which have ravaged our flocks* and herds. All those who raise or own animals are vitally interested in the preservation of their health and the preven*tion of disease. The inestimable value of these scientific* researches as to the prevention and cure of disease among human beings it is superfluous for me to point out. Modern surgery and the antitoxin treatment of diphtheria alone would justify all the vivisection ever done." Undoubtedly the majority of the physicians in the United States are in accord with Dr. Keen's views, and it is to be hoped that the efforts of the American medical profession may be successful in defeating the Columbian Anti-Vivisection Bill. The anti-vivisectionists in America are chiefly composed of unscientific enthusiasts or of notoriety mongers

Rapid Transit for New York City.

The means employed in New York to convey passengers have long been remarkable for their inadequate accommodation at certain periods of the day as well as for many insanitary features. The modes of locomotion chiefly in vogue are the overhead steam railways and on the level street-cars propelled by electricity. The elevated railways are in several respects a disgrace to a city of the size and wealth of New York and have been freely pilloried in the lay and medical journals. The stations are for the most part uncomfortable, dirty sheds; while the carriages themselves are lacking in many *points* usually considered necessary to health. In regard to the street system of transit much improvement has been effected of late, the cars in all the principal *thorough*fares are driven by electric power, and the comfort of passengers is fairly well looked after. Faults may be found with the methods of heating and ventilation and with some less important details, but the great blot on the whole system of locomotion in New York is the excessive over-crowding in the morning and evening at the time when people are going to and from their work. No limit is placed on the number of persons carried, and, the consequence is that a car calculated to seat 20 passengers will *for* an hour or two before and after business hours have at least twice that number inside and probably 20 outside, hanging on the steps or in any place where they can gain a footing. This state of affairs, as may be well imagined, does not conduce to the health, comfort, or temper of those who are obliged to make use of one or other of the *transit systems of* New York, *and the cry has for* a long time been that radical reforms must be introduced. The fact is perfectly plain that the only really effectual remedy will be to relieve in some way the overgorged traffic. It is just as evident that this desirable relief can be brought about but in one manner, which is by introducing an underground system. The capitalists interested in the existing methods of transit have fought long and vigorously against this innovation, but have apparently been beaten, for the news has gone forth that the contract has been given for a tunnel measuring several miles and costing $30,000,000 to run through the heart of New York.

Medical News in American Lay Journals.

A prominent feature in up-to-date American lay journalism is the great interest which is taken in medical matters. This is doubtless done mainly for sensational purposes, and the *more* gruesome the account *of some simple surgical* operation given by the reporter the better does it suit the literary palate of a certain class of readers. Often it happens that the reporter makes ludicrous mistakes which, of course, are read with some amusement by members of the medical profession. Dr. Nelson W. Wilson of Buffalo, writing on the subject in the *American Medical Quarterly* for September last, gives some laughable instances of mistakes made by journalists who were ignorant of medicine or of the anatomy of the human body. Dr. Wilson speaks of the first instance that came under his notice as follows: "One of the most amusing errors which I have seen recorded in print appeared in a Buffalo newspaper. The reporter, who was young, was present at an autopsy and was deeply interested. *As* the *organs* were removed he was told what they were. He expressed surprise at the size of the liver. There was a pathological condition of *the spleen which* excited *comment among* the examiners. The reporter shortly afterwards left. The next issue of his newspaper contained this statement: 'A curious condition existed. *In* addition to the liver being very large a smaller liver was found some distance away in the left side of the body.' A physician who was 'sterilising catgut in boiling alcohol' had the misfortune to set fire to his clothes. A New York paper described the after events in the following lurid terms: 'Across the lawn to the operation section he wildly ran, the flames enveloping him from head to foot. Unannounced, the man of flames threw open the door of the operating-room, dashed in among physicians, nurses, and attendants, who were busy performing a delicate operation on a *morphine unconscious woman, and before* they recovered from their fright the man was so seriously burned that his recovery is most improbable. When Dr. —— entered the *operating-room* the *surgeons were at* the most critical stage of their work "Save!" he yelled to the chief surgeon as he bolted into the room, "or I will be burned to a *crisp*." ..... *It is a remarkable thing* that the young woman on the operating table never recovered consciousness during all the excitement She was entirely oblivious of all the exciting events that transpired until she came to and was told of them. It is doubtful whether she would have stood the fright if she had come to when the burning man had rushed into the room'" Dr. Wilson relates many more accounts of medical and surgical happenings as told in American lay journals, but the preceding will suffice to show that the American reporter if not to be relied upon for accuracy is well able at least to provide reading for the patrons of his newspaper which will compare with that of any papers in the world for word painting.

Feb 10th.

Obituary.

PROFESSOR LUDWIG MEYER.

WE regret to learn that *Professor Ludwig Meyer*, Director of the Provincial Asylum and of the University Clinic at Göttingen, died at his post of duty on the 8th inst. *Professor* Meyer was a distinguished physician in the department of mental medicine and early in life he strenuously adopted the non restraint principles advocated by Dr. Conolly. In 1866 he was promoted from Hamburg to Gottingen and throughout his long and active life he maintained his position in the forefront of scientific and administrative work. Professor Meyer wrote many articles on subjects connected with nervous and mental diseases which commanded respectful attention. He was specially proud of the institution of clinical wards in connexion with the German universities for the purposes of teaching and treatment. His enthusiasm and devoted attention to duty was an inspiration to those who were fortunate in his friendship, and his death will be deeply felt by his colleagues at home and abroad.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gabriel Tourdes of Nancy, aged 90 years. He was the son of a professor of medicine in the old Strasburg Faculty in which he himself afterwards held the combined chairs of Forensic Medicine and Pathology until the organisation of the German University of Strasburg after the war in 1871. He then migrated to Nancy, in which faculty he held the chair of Forensic Medicine until 1888, since which he has lived in retirement. He was a somewhat prolific writer on medico-legal topics and also on medical geography.—Dr. Philipp Knoll, who was recently appointed to the chair of General and Experimental Pathology in Vienna. He had previously held a similar post in the German University of Prague where he was the means of establishing a laryngological institute. He wrote a large number of papers on various subjects connected with experimental pathology. In addition to his scientific labours he found time to carry on an energetic political campaign in the interests of the German as opposed to the Bohemian population of Bohemia.—Dr. Albert Edward Hoadley, professor of Orthopædic Surgery in the Chicago College of Physicians and Surgeons.—Dr. O Widman, extraordinary professor of Medical Pathology in the medical school of Lemberg.—Dr. Coste, formerly a French senator.—Dr. Charles Delstanche, lecturer on Aural Surgery in the University of Brussels, aged 59 years.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations and conformed to the by-laws, have been admitted Members of the College:—

Alfred Parker Ambrose, Westminster Hospital, Miguel Arango, University of Bogota, Columbia; Frank Atthill, Charing cross Hospital, William Edward Bamber, Owens College and Royal Infirmary, Manchester; Lionel Jasper Bartlett, St. George's Hospital; Basil Sorley Bartlett, Francis Reinagle Barwell, and William Bastian, University College Hospital; Hugh Wansey Bayly, Cambridge University and St. George's Hospital; Frank Miller Bingham and Edward Wemyss Browne of St. Thomas's Hospital; Anthony Fewster Blake, London Hospital; Francis Dawson Blandy, Middlesex Hospital; Hubert Penrose Bradley, Cambridge University and London Hospital; William Philip Sutcliffe Branson, Cambridge University and St Bartholomew's Hospital; Clement Arthur Douglas Bryan, Guy's Hospital Edward Payton Burns, Queen's and General Hospitals and Mason College, Birmingham; John Cameron, Edinburgh University; Thomas Chetwood, London Hospital; Harry Norman Rix Child, University of New Zealand and Middlesex Hospital; John Aylward Churchill, St. George's Hospital; John Moore Collyns and Charles Vivian Cornish, St Bartholomew's Hospital; Walter Edward Cooper, University College Hospital; Gilbert Edgar Cope, Westminster Hospital; John Francis Cunningham, St Thomas's Hospital, Henry Newcombe Clarke and Autrey Hugh Davies, Cambridge University and Guy's Hospital; Percy Clarence Douglas, St. Mary's Hospital; Henry Durbridge, Guy's Hospital, Gerald Meade Eastment, Middlesex Hospital; Frederic George Henry Edwards St. Thomas's, Middlesex, and London Hospitals, Thomas Crisp English, St George's Hospital; Robert Fell and Henry Bertram Foster, Guy's Hospital; Herbert Wortley Fisher, London Hospital, John Edmund Francis, University College Hospital, William Varé Chalmers Francis, Westminster Hospital, Thomas Gillespie, Cambridge University and St. Bartholomew's Hospital, Guillermo Gomez, University of Bogota, Columbia, Arnold Saxty Good, St. George's Hospital; Nathaniel Grece, McGill University, Montreal, and St. Bartholomew's Hospital, Wilfred St. George Grantham-Hill, Ernest William Holyoak, and John William Hunt, St Mary's Hospital; William Henry Harland, Middlesex Hospital, Owens College, and Royal Infirmary, Manchester, Francis Raymond Mitchell Heggs, Mason College, Birmingham, St. Mary's and London Hospitals, Richard Farrar Hiley, Cambridge University and St. Thomas's Hospital, Edward Falkner Hill, Owens College and Royal Infirmary, Manchester, Samuel Prince Hopewell, London Hospital; Richard Rotherwell Horley, Middlesex Hospital; Edmund Hudson, Owens College and Royal Infirmary, Manchester, and St. Thomas's Hospital; John Warwick Illius, St. Bartholomew's Hospital; Orlando Inchley, and Arnold Woodford Izard, Cambridge University and St. Bartholomew's Hospital; Frederick Burroughs Jefferiss, King's College Hospital; Robert George Johnson, University College and Royal Infirmary, Bristol; Joseph Edward Judson, Owens College and Royal Infirmary, Manchester; Stanley James Kerfoot, London Hospital; Robert Blair Kinloch, University College of South Wales, Cardiff, and St. Thomas's Hospital; Charles Lees and Percy Augustus Longhurst, Charing Cross Hospital; Harold Samuel Libby, St. Thomas's Hospital; Llewellyn Lindop, St. Mary's Hospital; Charles Thomas McClure, London Hospital: William Augustine McEnery, Richard William Herbert Meredith, and Percival Thomas Nicholls, Middlesex Hospital; Oswald Marriott and Bertram Wilmore Moss, Guy's Hospital; Herbert Alfred Mason, Firth College and General Infirmary, Sheffield; Leonard John Pavillet Mordaunt, St Mary's and Charing Cross Hospitals and Edinburgh University; John Wilfred Nunn, St. Bartholomew's Hospital; Harold Rothery Nutt, St. Mary's Hospital; Herbert John Orford, Mason College and Queen's and General Hospitals, Birmingham; Vivian Bernard Orr, Melbourne University and Westminster Hospital, Thomas Dainly Paddock, University College and Royal Infirmary, Liverpool; William Hodgson Park, Charing Cross Hospital; John Frederick Paul, St. George's Hospital; Allan Campbell Pearson, Cambridge University and St George's Hospital; William Edward Peck, University College Hospital; Claud Maxwell Pennefather, Durham University and St. Bartholomew's Hospital; Sydney Pern, St Thomas's Hospital; Charles Ayre Peters, McGill University, Montreal, and St. Bartholomew's Hospital; Henry George Pinker, St. Bartholomew's Hospital; Redcliffe Nathan Salaman, Cambridge University and London Hospital; James Herbert Sanders and George Herbert Spencer, London Hospital; Edward Mells Saunders, King's College Hospital; Michael Sheehan, Queen's College and Northern Infirmary, Cork; Alfred Ernest Softly and Henry Zouch Stephens, St. Thomas's Hospital; Alfred Richard Spencer and Edmund Hamilton Blake Stanley, University Cottage Hospital; Philip Graham Stock, University College and Royal Infirmary, Bristol; William Sutherland, University of New Zealand and University College Hospital; William Benjamin Batchelor Taylor and Henry Thwaites, London Hospital; Christopher Thackeray, Firth College and General Infirmary, Sheffield, and Owens College and Royal Infirmary, Manchester; Bernard Renshaw-Beckit Truman, Cambridge University and St. Bartholomew's Hospital; Walter Edward Turner and Alfred Dittop Benedictus Von Rosen, St. Mary's Hospital, John Valérie, St. Bartholomew's Hospital; Robert Alexander Walker, Cambridge University and St. George's Hospital; Richard Warren, Oxford University and London Hospital; Robert Nimmo Watson, Westminster Hospital, Charles Herbert Welch, University College and Royal Infirmary, Bristol; William Reginald Eyton Williams, Edinburgh University and Guy's Hospital; Richard Le Geyt Worsley, St. George's Hospital and Durham University; Thomas Preston Yates, Owens College and Royal Infirmary, Manchester.

UNIVERSITY OF CAMBRIDGE.—At the congregation held on Feb. 15th, the graces proposing to abolish the order of merit in the Mathematical Tripos were rejected. The following medical degrees were conferred:—

M.B. and B.C.—A. C. Fry, Pembroke; H. Glasier, Emmanuel.
B.C.—H. M. Harwood, Trinity, J. A. Nixon, Caius.

PRESENTATIONS TO MEDICAL MEN.—At the Institute, Woburn Sands, Beds., on Feb 9th, Mr. Robert L. Brander, M B. Aberd., of Aspley Guise, Beds, was presented with a testimonial for his meritorious medical attendance on the night of Nov. 23rd last, on a well-sinker, who was entombed for some time while working in a shaft, the sides of which collapsed. Dr. Brander was sent for, and on seeing the body he made strenuous efforts for several hours to produce resuscitation, but life was extinct. Recently, in remembrance of Dr. Brander's exertions on the occasion, it was thought they deserved some public recognition; accordingly subscriptions for that purpose were collected, to which friends and the villagers generally in the district freely responded, the result being the presentation of a purse containing money and an illuminated address.—Mr. William C. Smith, M.B. Edin., of Great Harwood, Lancashire, was the recipient of a pair of binocular field-glasses on Feb. 6th from the members of the local golf and union clubs as a farewell offering on his leaving for the front in the South African war.—On Feb. 14th, at the Municipal Offices, Liverpool, Mr. E. P. Manby, M D. Cantab., the assistant medical officer of health, who is about to leave for London, having been appointed on the medical staff of the Local Government Board, was presented with an inkstand, suitably inscribed. Dr. Hope, in making the presentation on behalf of the staff, wished Dr. Manby every happiness and success in his new position.—On Feb. 13th the members of Court Perseverance of the Ancient Order of Foresters, Bath, presented Mr. J. W. Wigmore, M.D. R U.I., with an inkstand engraved with the following inscription: "Ancient Order of Foresters, Feb. 13th, 1900. Presented to J. W. Wigmore, Esq., M.D., on his resigning the duties of medical officer to Court Perseverance after 20 years' faithful service."

HOME FOR INEBRIATES AT CARDIFF.—At the meeting of the Cardiff Watch Committee held on Feb. 14th a sub-committee recommended that 10 acres of land should be purchased and that a home to accommodate 50 inmates (25 of each sex) should be erected at a cost of £10,000. The cost of maintenance was estimated at 15*s.* per patient, towards which the Government allow half a guinea, and it is considered that the annual expenditure would be about £830. The committee unanimously adopted the report.

FREEMASONRY.—The installation meeting of the Phœnix Lodge, 904, has just been held at the Masonic Buildings, High-street, Rotherham, when the new Worshipful Master, Bro. Charles A. Locke, L.R.C.P. Lond., M.R.C.S. Eng., Dist. Assist. G.D.C., Barbados, Senior Warden, who had been elected at the regular lodge meeting in January, was installed into the chair of the lodge by W. Bro. James Mellors, the retiring Master, assisted by W. Bro. John Gibbs, P.M., P.P.G. Treasurer. There was a large attendance and after the ceremony about 60 brethren dined together.

THE forty-third annual meeting of the subscribers and friends of the Bradford Eye and Ear Hospital was held on Feb. 16th, the Mayor of Bradford presiding. The hospital draws patients from a very wide area, the number during the past year being 6126, of whom 907 were treated for diseases of the ear. There have been 992 in-patients, giving a daily average of 27 and an average stay of 10 days. The number of major operations was 970, of which 116 were flap extractions of senile cataract and 28 removal of lens for high myopia. The number of out-patient attendances was about 15,000, necessitating now a daily attendance in that department. The income was £2454 and the expenditure £2835. The hospital has invested funds amounting to £15,000.

A NEW ISOLATION HOSPITAL FOR SOUTHAMPTON.—On Feb. 12th the Mayor of Southampton, Alderman G. A. E. Hussey, formally opened the new isolation hospital for Southampton which the town council decided upon erecting so far back as 1896. The buildings stand upon a site of 10 acres, having a loam and gravel soil. At present the buildings consist of an entrance lodge, an out bathing station, a mortuary, an administration block, and four pavilions of wards. In all there are 72 beds. Besides these buildings there are a laundry and an ambulance block, with stables, coach-house, and rooms for the male staff. The wards are floored with polished narrow battens of pitch pine and all angles are rounded off. The walls are cemented and painted a pale apple-green colour. All the buildings with the exception of the ambulance block are lighted with electricity. Southampton stood particularly in need of an isolation hospital owing to the prosperity of the place depending in such large measure upon the docks. It is thus specially exposed to the chance of infection from without and unless it is known that every precaution is taken against the spread of infection great injury would accrue to the shipping industry and thus to the trade of the port.

PUBLIC HEALTH IN HONG-KONG.—In his annual report for 1898 Dr. F. W. Clark, the medical officer of health of Hong-Kong, states that the estimated population of the colony in the middle of the year was 254,400, including Chinese, 239,210; non-Chinese civilians, 8732; army, 3073; and navy, 3385. No less than 70·9 per cent. of the Chinese population and 58·6 per cent. of the non-Chinese population are males, while considerably more than the half of both classes are between the ages of 20 and 45. The population of the city of Victoria is given as 164,250 Chinese and 6950 non-Chinese. The city is divided into 10 health districts, in two of which, covering each an area of 23 acres, there is extreme overcrowding, the number of persons per acre being 982·3 and 760·5 respectively. The number of births registered during the year was 1206, giving a general birth-rate of 4·7 per 1000 as compared with 5·5 per 1000 in 1897. In this colony there is a great preponderance of male over female births; in Great Britain and in temperate climates generally the proportion is 104 male to 100 female births, but in Hong-Kong the proportion is among the white races 128 males to 100 females. The total number of deaths registered during the year was 5874, as compared with 4688 during 1897. The death-rate for 1898 was therefore 23·3 per 1000. The total deaths among the Chinese were 5383, or 22·5 per 1000. The death rates in the non-Chinese community were 16·2 per 1000 among the white races and 33·6 per 1000 among the coloured races. Plague caused 1128 deaths among the Chinese, 40 in the non-Chinese civilian community, and three in the army. Small-pox caused 99 deaths among the Chinese, 11 in the non-Chinese civilian community, and one in the navy. Beri-beri caused 117 deaths, all among the Chinese.

VACCINATION GRANT.—Mr. Philip E. Hill, M.R.C.S. Eng., public vaccinator to the Crickhowell District of the Crickhowell Union, has been awarded the Government grant for successful vaccination for the eleventh time in succession.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Petroleum Question.

THE Government has made it known that it does not see its way to introduce during the present session of Parliament legislation with reference to accidents arising from the use of petroleum lamps. A Bill, however, has been brought in by a private Member for the raising of the statutory flash point of petroleum oil.

The Inebriates Act in Scotland.

There is in course of passage through the House of Lords a Bill designed to strengthen the administration of the Inebriates Act in Scotland. It confers on the local authorities increased powers of assistance for the establishment and maintenance of inebriate reformatories, and it makes eligible for committal to these institutions persons convicted of drunkenness and disorderly conduct in a public place.

HOUSE OF LORDS.

THURSDAY, FEB. 15TH.

Isolation Hospitals.

The Earl of LICHFIELD, in moving the second reading of the *Isolation Hospitals (Amendment) Bill* explained that the object of the measure was to improve the facilities for the provision of sufficient isolation hospital accommodation. The Act of 1893 empowered county councils to provide isolation hospitals and to group districts together for that purpose. The Local Government Board, however, had decided that where a local authority had already provided sufficient hospital accommodation, although it was willing to be included in a hospital district, it could not sell or lease its existing hospital to a hospital committee constituted under the Act of 1893. It was chiefly to remedy this that the Bill was introduced, and he urged the Local Government Board to take the Bill up so that it might pass the House of Commons.—Lord HARRIS intimated that the Local Government Board had no objection to the Bill and said he would bring the request of the noble Earl before Mr. Chaplin.—The Bill was read a second time, and at the following sitting the House passed it through Committee without amendment.

The Medical Examination of Volunteers.

Earl BROWNLOW called the attention of the House and the Government to the inconvenience caused by the rejection of Volunteers for service in South Africa by the army medical officers after the men have got their clothing and equipment. The noble Earl spoke of men having to crawl home to their native towns in humiliation and disgust.—The Marquis of LANSDOWNE, after expressing sympathy with the complaint, intimated that a regulation to this effect had been drafted—viz.: "When a Volunteer commanding officer receives an application from any Volunteer he will at once have him medically inspected, and when he has received sufficient applications from Volunteers who have been passed medically fit to form not less than a section he will so inform the officer commanding the regimental depôt to which the battalion is affiliated, who will then have them attested." To this he proposed to add "medical inspections may be carried out by any medical officer holding a commission in any force of Her Majesty's service."

HOUSE OF COMMONS.

THURSDAY, FEB. 15TH.

The Purity of Oysters.

Mr. CHAPLIN, in reply to a question on this subject, said that he did not think it would be possible to introduce an Oysters Bill during the present session. He was glad, however, to be able to say that very considerable improvements had been made in the oyster-beds and that further improvements were in contemplation.

Introduction of Sir Michael Foster.

The new representative of the University of London, Sir Michael Foster, was introduced by Mr. Jebb and Sir William Anson and took the oath and his seat. The two sponsors are representatives respectively of Cambridge and Oxford Universities.

FRIDAY, FEB. 16TH.

Medical Appointments in Londonderry.

Mr. ARTHUR MOORE asked the Attorney-General for Ireland whether the attention of the Irish Government had been drawn to the fact that almost all the public appointments in the city of Derry were in the hands of the Protestant minority; and whether, in view of the vacancies caused by the death of Sir William Miller, due consideration would be given to the claims of Roman Catholic and Nationalist medical men before filling these appointments.—Mr. ATKINSON: The meaning expression "public appointments" in the first clear. If the hon. Member refers to the officers of local bodies I would remind him that these officers are appointed independently of the Government. And as regards the officers whose appointments are subject to the control of the Government I have no information as to the politics or religion of such officers. With respect to the second paragraph the legitimate claims of all candidates will be carefully considered.

Deaths from Disease at the War.

Sir WALTER FOSTER asked the Under Secretary of State for War whether he could state approximately the number of deaths from disease among the forces serving in South Africa and if possible the number of those who had succumbed to enteric fever.—Mr. WYNDHAM: The figures are approximately—deaths from enteric fever 240, deaths from other diseases 268, making a total of 508.

Infectious Disease in the Post Office Service.

Sir WALTER FOSTER asked the Secretary to the Treasury, as representing the Postmaster-General, whether servants of the Post Office were compelled to notify to the department the outbreak of infectious diseases in their homes; and whether such officers were generally prevented from performing their official duties, and compelled to remain away from office until medical sanction was given, whether a regulation had recently been issued stating that this enforced absence would be treated as sick leave, and whether he could state if it was intended to count this time when an officer's superannuation, owing to illness, was being considered.—Mr. HANBURY: Post office servants are required to report to their superior officer any case of scarlet fever, small-pox, typhus fever, cholera, diphtheria, measles, or typhoid fever, occurring in their homes. Should the case be one of the first four of these diseases the man is not allowed to attend for duty; but this practice is not maintained as regards diphtheria, measles, or typhoid fever, except under special circumstances. Full pay is allowed in all cases of compulsory detention from duty from the above causes; but in calculating the amount of sick leave which an officer may receive on full pay during the year, the period of any such compulsory absence is included.

MONDAY, FEB. 19TH.

The Report of the Malarial Commission.

Mr. WEIR asked the Secretary of State for the Colonies whether he could say when the report of the Malarial Commission would be issued, and would he state whether Her Majesty's Commissioner had yet advised the establishment of a sanatorium in the Shire Highlands, British Central Africa.—Mr. CHAMBERLAIN: The report is not expected before the close of the year. The question of a sanatorium in the Shire Highlands has not been raised by Her Majesty's Commissioner. There is a hospital at Blantyre of which the Administration will assume control on April 1st next, and a staff of nurses paid from Protectorate funds.

The Removal of Casualty Cases in Glasgow.

Sir CHARLES CAMERON asked the Lord-Advocate whether the Scottish Local Government Board had yet considered the change of practice recently introduced in Glasgow in dealing with cases of debility and injury brought to the police offices, and subsequently removed to the parochial hospital, whereby pauper patients were removed to that hospital without any certificate from the parochial medical officer of their fitness for removal; whether the criminal authorities had sanctioned the inspection of the private police books by the parochial officers; and whether the removal of a moribund person on the data contained in these books, and without certificate from the parochial medical officer, would be held to satisfy the requirements of the Poor-Law Act, and on whom, in case of mishap occurring in connexion with a removal so conducted, would legal responsibility rest.—The LORD-ADVOCATE: I am informed by the Local Government Board that they have inquired, and find that a slight change of practice has taken place in regard to cases occurring during the night in the portion of the amalgamated parish formerly the City Parish of Glasgow. These cases used to be removed direct to the poorhouse by cab, &c., by the police, and were admitted without communication with the parochial authorities or a certificate of any kind. Now a telephone message is sent to the parochial chambers and the poorhouse ambulance is used for the conveyance of the person to the poorhouse on the casualty surgeon's written recommendation. Casualty surgeons have been instructed to enter in a book kept by them their opinion whether the patient can be safely removed, and such book is to be available to the inspector of poor or his representatives before removing any patient from the police offices to the poorhouse. I may add that the Local Government Board consider this system to be a great improvement on the previous system, and I see nothing in it contrary to the requirements of the Poor-law Act.

TUESDAY, FEB. 20TH.

Medical Organisation for the Army.

Dr. FARQUHARSON asked the Under Secretary of State for War what steps were proposed to be taken in connexion with the scheme of the Government for increasing the efficiency of the Army to create a proper effective medical organisation for the Militia, Yeomanry, and Volunteers, and would it be represented at the War Office by proper staff officers; and if it was proposed to give effect to the numerous recommendations to the War Office to create the bearer companies of the Volunteer infantry brigades separate units, independent of any particular regiment or regiments of the brigade.—Mr. WYNDHAM: This subject is one of the many connected with the organisation of the Auxiliary Forces which are now being considered.

PRESERVATIVES AND COLOURING MATTERS IN FOOD.

EVIDENCE BEFORE THE DEPARTMENTAL COMMITTEE.

WEDNESDAY, FEB. 7TH.

The Committee met again to-day with Sir Herbert Maxwell in th chair.

Mr. ROBERT GIBSON, salesmaster of the Public Creamery Market in Limerick, examined by the Chairman, said that he had been fully 40 years in the butter trade and his experience told him that the use of preservatives was necessary in Ireland. He had tried again and again to do without them and he had always failed to satisfy his customers and had been compelled to fall back upon preservatives. Irish butter had always had a name for keeping, and in consequence it was not treated by customers in the same way as Danish or Normandy butter—that was to say, the Irish butter was kept on hand, while the Danish or Normandy was disposed of quickly. He had a customer in Grantham who kept the butter for four months and who said that it tasted as well at the end of that time as when he received it from Ireland. So satisfied was the witness that preservatives were necessary and that they were wholesome, that all the butter under his control now contained them. The butter he himself ate contained 1 lb. of boric preservative to 112 lb. of butter, which produced an article capable of keeping sweet for at least a month. When he used to eat butter without this preservative, and of course containing salt, he found that he had to take several drinks between meals—not intoxicating drinks, for he was a teetotaller—while now that he ate butter with boric preservative, these between-meal drinks were no longer necessary. His opinion was that for the health of the community and for its pocket the use of preservatives had been an immense advantage. The community were well aware of the practice and therefore there could be no objection to a declaration of the presence of preservatives in butter. On the subject of colouring butter the trade in Ireland was divided.

By Dr. TUNNICLIFFE: The butter he had referred to as keepin sweet for four months contained 1 lb. of boric preservative t 112 lb. of butter, which never worked out on analysis at more tha 0·8 per cent.

Dr. A. GRUNBAUM, lecturer on chemical physiology in the Universi College, Liverpool, said, in answer to the CHAIRMAN, that when he a Professor Boyce were recently on the Continent in connexion with the Sewage Commission they made inquiries as to food preservatives in France, Belgium, Germany, and Austria, but principally in the last two countries. In Germany he found that the law as to food and drugs was hardly more definite than it was here, but there was a circular issued by the Ministry of the Interior and two other Ministries to the various presidents of provinces in which it was said that the addition of preservatives to milk should be prohibited. As the result of this circular by-laws were made and these were put in force by magistrates against whose decisions there was always the right of appeal. As regards wine there was a definite law which prohibited the use of certain substances such as salicylic acid. In the case of the city of Hamburg, on every occasion when boric acid preservative was found in milk there was a prosecution followed in the great majority of cases by a conviction, and the same state of things prevailed in other places. A favourite preservative in Germany was sodium sulphite in minced meat and for its use punishment up to six weeks' imprisonment had been inflicted. In Vienna the law did not actually say that boric acid or formalin or anything of the kind was not to be added to milk but by-laws did so, and lately the city of Vienna got expert opinion on the subject to the effect that these preservatives should be forbidden. It might be taken that the general drift of opinion in Germany and Austria was against the use of these preservatives. For instance, a law was now being formulated in Prussia in which the addition of borax or boric acid preservative to meat would in all probability be prohibited. In Switzerland there was a direct prohibition against the importation of meat with the addition of borax or boric acid.

By Dr. BULSTRODE: He should say that preservatives in milk had been prohibited in Germany on the general idea that they, as a whole, would prove injurious or might prove injurious. In 1884, when the circular he had mentioned was sent out, it was stated that the addition of preservatives would particularly be likely to injure children. It was only occasionally that formalin was found in Germany. In Hamburg it had only been found once although it had often been looked for, while as to salicylic acid it had been found two or thre times but not within the last year. He could not say whether th legislation of prohibition in Germany was based upon the evidence o expectation or upon experimental evidence, though in the case o sodium sulphite he knew that various experts had given evidence as t the symptoms which follow its administration. The use of sodiu sulphite in minced meat was condemned because among other things made stale meat look like fresh and because the food was largely us for invalids. The general trend of the medical evidence was th this material caused diarrhœa and indigestion. In Germany it had be decided that the amount of sulphate of copper required to colour p was so small that it would not have an injurious effect, and the use sulphate of copper for this purpose in minute quantities was prohibited. He found that the medical profession in Germany ha strong feeling that the addition of these preservatives was undesira They based that feeling on general principles and on the desirabilit the medical man knowing what his patients were taking. The cit Berlin, with a population, roughly speaking, of 1,500,000, was supp with milk free from preservatives.

By Dr. TUNNICLIFFE: Both in Germany and in Austria there w law forbidding the use of preservatives in beer.

By the CHAIRMAN: It seemed to him that on general grounds servatives should be forbidden because, so far as they knew, wha injurious to bacteria was also injurious to the cells of higher deve organisms, and although in the latter case they were capa replacing, which bacteria would not be, it did not appear to hi the higher developed organisms should be called upon to repla which had been destroyed by disinfectants. He thought that they aim not at antiseptic food but at aseptic food, just as in surge aimed at aseptic surgery. The great point with him was that th not yet got any antiseptic which while killing bacteria wo injure living cells. Declaration of the presence of a preservativ in his opinion, be an advantage. He agreed that much w learned from experiments on lower animals, but it seemed th lower animals stood unnatural additions to food better tha beings.

The Committee then adjourned.

DAVIS.—On Feb. 18th, at his residence, Crawford-square, Londonderry, Thomas Davis, M.D., J.P., aged 82 years.

HEATH.—On Feb. 15th, at Exminster, Devon, aged 34 years, Alan Jasper Heath, M.B. Lond., Captain in the Indian Medical Service (Bombay), second son of Christopher Heath, F.R.C.S., Cavendish-square.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SHOULD HOSPITAL PATIENTS SMOKE OR PLAY CARDS?

AT the annual meeting of the governors of the Hunts County Hospital at Huntingdon on Tuesday, Mr Sweeting moved that a new rule to the effect that *any patient guilty of misconduct should be liable to* dismissal be substituted for Rule 65, which specified certain particular offences for which patients might be dismissed, including among them smoking and playing cards. He said the old rule seemed obsolete. He really saw no reason why a patient should not be allowed to smoke where it could be done without discomfort to other patients, and playing cards, he thought, might be a most desirable recreation for the patients at times Mr Layton seconded the motion. Mr Tillard opposed it Who, he asked, was to say when smoking would be a discomfort to other patients? If arrangements could be made for separate rooms for smoking it might be more feasible but he could conceive nothing worse for a patient to whom the smell of tobacco was obnoxious than to have to endure other people smoking With regard to cards, he was fond of playing cards, but he could not forget that one of the greatest curses of the country was gambling and he believed gambling with cards was on the increase There were plenty of other amusements. Books, halma, draughts, and other games were provided, and he did not see why it was necessary to introduce cards. Mr Heathcote said he was rather in sympathy with Mr Sweeting's motion, but he thought it might have a tendency to encourage things which it was not desirable should be encouraged The Chairman (the Earl of Sandwich) said he must admit that the old rule savoured somewhat of the last century If ever he were admitted as a patient at the hospital, judging from the experience of his past life, the two things he would like to do would be to smoke and play cards. There were *several* wards and he did not presume that anyone would be entitled to smoke at any time without permission. There were certain wards where he thought smoking could go on without the smallest discomfort to anyone As for cards, he did not think they were likely to encourage gambling If *there were any tendency to* gambling the cards *could* be stopped by any authority in the hospital, but he did not think they need invent any misdemeanours which were not likely to arise Archdeacon Vesey said the matron, not knowing of the old rule, had allowed smoking at certain hours and thought it was a good thing It was of course stopped if there were any patient in the ward whom it would affect. With regard to cards he agreed that nothing should be done to encourage gambling in any form, but if it were a comfort to any of the patients and it were clearly understood that there should be no playing for money he did not see any difference between playing cards and playing halma or dominoes. *He was* inclined to think the rule should be a wide one so as to leave control in the hands of the matron Mr Sweeting's proposal to substitute the new rule was then carried.

We are very glad to see that the governors of the Hunts County *Hospital* arrived at the conclusion *to allow* both cards and smoking Recreation is of itself a great aid in the restoration of health and anyone who has been ill and is a smoker knows how pleasurable is the first pipe after a long illness It will of course be necessary to take care that smoking is not indulged in by some patients to the *annoyance or injury of others, and if it is allowed* in the wards we think that a limit should be put. With regard to cards we quite agree with Archdeacon Vesey, and we would add that if men want to gamble they will do it and nothing can stop them. Cards are not necessarily the devil's books and their legitimate use might lighten many a weary hour in a hospital *Apart from* any moral view *of* the propriety or otherwise of playing for money, a hospital patient certainly should not do so, for if he can afford to part with any money it should certainly be employed in paying for his maintenance in the hospital

LUNACY FEES.

To the Editors of THE LANCET

SIRS,—I have on two occasions certified insanity The relieving officer states he can only accept certificates from the parish doctor He notifies the parish doctor, who visits the patient and then notifies it Is the relieving officer correct in not accepting certificates from private practitioners?

I am, Sirs, yours faithfully,

Stamford hill, N.

M D

⁂ Our correspondent is not explicit enough as to what certificates he refers to If he alludes to a notice of "alleged" lunacy the relieving officer is of course bound without choice to accept notice from any medical man If he refers to a certificate of unsound mind for the purposes of removal to an asylum the choice of the medical man in these circumstances rests with the justices. Under the Lunacy Act it is the justice who calls in any practitioner he chooses to examine and report (i e., to certify as to the mental condition) in every case of lunacy, of which information is laid before him by the relieving officer. The question of what medical man is called in and what fee is paid remain absolutely in his discretion Since the relieving officer is constantly in relation with the justice the latter sometimes accepts the suggestion of the relieving officer as to which medical man should be called in, but most justices are very rightly jealous of their power and would at once check any such suggestion from a relieving officer The justice is certainly not bound to call in a parish medical officer, though the parish medical officer is often selected because he happens to know most about the case Many justices employ their ordinary medical attendant, a practice that *is open to misconstruction But it is quite clear that the relieving* officer has not any power in the matter, He is merely the agent of the justice to carry out his orders —ED L.

PRACTICE AT MONTE CARLO

To the Editors of THE LANCET

SIRS,—I should feel greatly obliged if you could give me any information with regard to practising at Monte Carlo. (1) Is the M R.C.S, L.R.C P. London accepted? (2) Is an M D degree necessary? and (3) If so, is the M D Brux recognised? I should *feel* greatly obliged for any information on the above

I am, Sirs, yours faithfully

Feb 15th, 1900

R. S

⁂ The right to practise in Monaco is held by permission of the Prince of Monaco who gives it when he thinks *fit* and withdraws it when he thinks fit. The right is, in fact, a personal favour —ED L.

A GREAT OPPORTUNITY

THE following advertisement has appeared in a Liverpool paper recently:—

> "Friendly society, with about 250 members residing in Liverpool and district, require the services of a qualified Medical Officer from the 1st of April next; must reside in a central part of Liverpool —For particulars *apply to Wm. Stainton, Pilotage Office, Liverpool.*"

In answer to the advertisement a medical man wrote for particulars and received the following letter from the Liverpool Pilots Benevolent Society:—

> Duties, &c., of Medical Officer
>
> Rule No 13.—"The Surgeon for the time being shall attend and provide at his own expense all medicines to any member of the *society when called upon or requested by* the stewards or other officers of the society Should he be engaged with other patients and unable to attend personally he shall provide a substitute within an hour from the time of notice being left at his residence."
>
> Medical certificates free when required. Members reside in Liverpool or the suburbs and are employed in the *Liverpool Pilot Service* or are pensioned therefrom
>
> Salary £20 per annum, payable half yearly
>
> 22/1/1900
>
> W. STAINTON

We wonder how large the benevolent society is that gives such an income to its medical officer It seems to us that if this functionary were to happen to be engaged with other patients once a week or so when the pilots wanted him, he would *have to discharge* his duties at pecuniary loss to himself

THE CHOICE OF AN OPHTHALMOSCOPE

To the Editors of THE LANCET.

SIRS,—Would some of your readers tell me what ophthalmoscope they consider probably the most suitable for a country practitioner? *In* the lists of instrument makers there seems to be very many and I am in doubts which to purchase A word in THE LANCET would be *esteemed*

I am, Sirs, yours faithfully,

Feb. 17th, 1900

A LEADER

MEDICAL ATTENDANCE IN BOURNEMOUTH

IN a recent issue of the *Bournemouth Guardian* appears the following letter —

LOCAL DOCTORS.

SIR,—*In Bournemouth—even with its hundred* doctors—there is the utmost difficulty between 10 A M and 1 P M and 3 P M and 6 o'clock in getting any doctor at all They are all out on their rounds

I have often been on the point of writing to you on this subject. Just now the alarming *hiatus* was *brought home* to me in the road at noon by a breathless inquiry where a doctor could be found The applicant had been to several doctors' houses none of the medicos were at home.

Surely this ought not to be The faculty, amongst themselves, should by telephone and otherwise have such *an intercommunication* that a medical man could at any moment be procured

Judging by equipages, doctors, though they work hard, do not *fare ill in* Bournemouth, and they owe something to the body politic for shelter and affluence Not to be able to procure a doctor for at least six hours out of 24 in a town which (in the *main*) owes its success to the invalid is surely little less than a scandal

February, 1900

ONE OF THE AILING

Now this is an excellent instance of how the average ailing person regards a medical man—namely, as someone who should always be at his particular *beck and call* A medical man has his set times for

Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (3rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (26th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Adjourned Discussion on the Pathology and Treatment of Appendicitis.

TUESDAY (27th).—CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret-street, W.).—8 P.M. Dr. F. Warner: The Elements of Early Training.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. F. Parkes Weber: Acute Ménière's Symptoms in Spleno-medullary Leucocythæmia, with special reference to the Anatomical Changes found in Acute Leucocythæmic Affections of the Ear, including a Pathological Report on the present case by Mr. R. Lake.—Dr. H. Thursfield: The Skin Affections met with in Bright's Disease.

WEDNESDAY (28th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Ordinary Meeting.

THURSDAY (1st).—CHILDHOOD SOCIETY (7, St. James's-square, S.W.).—4 P.M. Annual Meeting. Rev. T. W. Sharpe: Address.

FRIDAY (2nd).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—Clinical Evening. The following Cases will be shown:—Mr. C. B. Keetley: (1) Radical Cure of Hernia 10 years after Operation; (2) Case of Excision of the Pylorus.—Dr. C. Pope: (1) Case of Bradycardia in a Child; (2) Case of Abscess of Spleen cured by Drainage.—Dr. S. Taylor: Case of Palsy of the Sixth, Seventh, and Eighth Cranial Nerves.—Dr. Abraham: Two Cases of Disease of the Skin.—Mr. Bidwell: (1) A Case of Nephro-lithotomy; (2) Two Cases of Pyloroplasty.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by the following:—Sir Felix Semon, Dr. Horne, Dr. Potter, Dr. Powell, Dr. StClair Thomson, Mr. Heath, Mr. Lake, Mr. Robinson, and Mr. Waggett.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Exhibition of Clinical Cases, Specimens, &c. (Living Cases will be shown first):—Dr. McCann and Dr. Ezard: Case of Ruptured Ovarian Cyst.—Dr. Adkins: A Case of Enteric Fever in which the whole of the Ulcers were transversely placed and Peyer's Patches not much affected.—Dr. Toogood: Cases from Lewisham Infirmary.—Mr. C. Williams: (1) Case of Caries of the Spine; (2) Cast, Specimen, and Skiagraph of Case of Congenital Hypertrophy of Great and Second Toes. Council Meeting.

SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Adjourned Discussion on the After-effects of Ether Inhalation on the Respiratory System (re-opened by Dr. Dudley Buxton).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (26th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. A. Keith: The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms.

LONDON THROAT HOSPITAL (204, Gt. Portland-street, W.).—4.30 P.M. Dr. Cathcart: Chronic Glandular Diseases of the Nose and Naso-pharynx. (Post-Graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Consultation. (Skin.)

TUESDAY (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Consultation. (Medical.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, W.C.).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

WEDNESDAY (28th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. A. Keith: The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—4.30 P.M. Dr. T. D. Savill: Lupus Erythematosus. (Post-graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—5 P.M. Dr. P. Manson: Malaria Parasites and Malarial Disease.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. H. Mackenzie: Pulmonary Cavities.

THURSDAY (1st).—WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—5 P.M. Clinical Demonstration:—Dr. D. Grant: Cases of Aural and other Forms of Vertigo.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. F. E. Batten: Demonstration of Selected Cases.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration of Surgical Cases. (Post-graduate Course.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

FRIDAY (2nd).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. A. Keith: The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. H. Spicer: Consultation. (Eye, Ear, Nose and Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND, IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1899, which was completed with the issue of Dec. 30th, and the Title-page to the Volume were given in THE LANCET of Jan. 6th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			
One Year	£1	12	6
Six Months	0	16	3
Three Months	0	8	2

TO THE COLONIES AND ABROAD.			
One Year	£1	14	8
Six Months	0	17	4
Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. J. Armstrong, Liverpool; Messrs. Armour and Co., Lond.; Mr. Abbott, Tunbridge Wells; Dr. A. W. M. Auden, Leigh; A. D. La T.

B.—Mr. R. D. Boase, Penzance; Bradford and West Riding Medical Union, Hon. Secretary of; Mr. E. Burney Young, Lond.; Messrs. Brand and Co., Lond.; Messrs. Bates Hendy, and Co., Reading; Birmingham Ear and Throat Hospital, Secretary of; Messrs. Burroughs Wellcome and Co., Lond.; Messrs. H. K. Bushell and Sons, Reading; Buntingford House Retreat, Herts, Medical Superintendent of; Sir T. Lauder Brunton, Lond.; Bristol Royal Hospital for Sick Children, Secretary of; British Colonial and Foreign Press Cutting Agency, Lond., Secretary of; Mr. C. Birchall, Liverpool; Mons. O. Berthier, Paris; Bell, Surbiton; Bradford Royal Infirmary, Secretary of.

C.—Mr. Jackson Clarke, Lond; Mr. A. Cooper, Lond.; Mr. K. Campbell, Lond.; Mr. F. Churchill, Lond.; Mr. A. H. Cheatle, Lond.; Messrs. T. D Charlesworth and Co, Lond.; Messrs Condy and Mitchell, Lond.; Messrs. A. H. Cox and Co., Brighton; Carmarthenshire Infirmary, Secretary of; Cantab, Lond.; Cumberland, &c., Lunatic Asylum, Carlisle, Clerk of; Messrs. Creswell and Creswell, Dowlais; Cheltenham General Hospital, Secretary of; *City Press*, Lond.; County Borough of Southampton, Medical Officer of Health of.

D.—Mr. F. Deas, Lond.; Mr. E. Darke, Lond.; Messrs. Duncan, Flockhart and Co., Edinburgh; Messrs Derry and Sons, Nottingham.

E.—Dr. J. Edmunds, Lond.; Mr. E. F. Eliot, Southampton; Messrs. Eason and Son, Dublin; Examination Hall, Lond., Secretary of. Mr. R. S. C. Edlestone, Nantwich

F.—Dr. F. T. B. Fest, Iriona, Honduras; Messrs. J. S. Fry and Sons, Bristol; Mr. A. L. Franklin, Coventry; Messrs. Fassett and Johnson, Lond.; Messrs. Farrington and Co., Lond.; F.R.C S., Lond.; Messrs. Ferris and Co., Bristol.

G.—Mr. W G. Groves, Woodford Green; Messrs Grafe and Sillem, Hamburg; Grape Vinegar Co., Lond.; Gazette News Co., Blackpool.

H.—Mr. H. D Hamilton, Ilford; Hastings, Clerk to the Borough of; Mr. G. Hermanni, Lond.; Miss Hubbard, St. Leonards; Mr. A. B. Hughes, Deal; Messrs. B. Heller and Co., Chicago; Dr. J. Hay, Liverpool; Mr. F. S. D. Hogg, Rickmansworth; Mr. F. Hutchins, Lond.

I.—Mr. P. A. B Isherwood, Ramsgate; Messrs. Ingram and Royle, Lond.

J.—Dr. J. Johnstone, Bolton; Mr. Vincent Jackson, Wolverhampton; Dr. Arthur James, Lond.; Mr. Mark Judge, Lond.; Mrs. A. Jones, Lond.; Mr. A. W. Jackson, Plymouth; J. H. M.; Dr. P. Jakins, Lond.

K.—Mr. C. W. Krohne, Lond.; Dr. J. Kerr, Bradford; Messrs. J. B. Keene and Co., Bath; Dr. A. B. Kelly, Glasgow.

L.—Mr. C. A. Locke, Rotherham; Messrs. Chas. Letts and Co., Lond.; Mr. R. M. Littler, Southport; Mr. W. M. Locke, Newport; Messrs. Lee and Nightingale, Liverpool.

M.—Mr. F. Middleton, Brighouse; Dr. G. Mackern, Buenos Ayres; Dr. J. M. MacCormac, Belfast; M.D., Chesterfield; Dr. A. M. Martin, Newcastle-on-Tyne; Mr. Christopher Martin, Edgbaston; Metropolitan Asylums Board Clerk of; Medical Society of Victoria, Melbourne, Secretary of; Mr. D. Mendora, Madrid; Mr. B. G. A. Moynihan, Leeds; Messrs. T. Morson and Son, Lond.; Maltine Manufacturing Co., Lond; Dr. A. W. Montgomery, Edmonton; Dr. H. C. Major, Bingley; Mr. W. Mackirdy, Sunderland.

N.—Dr. Richd. Neale, Lond.; Nottingham General Hospital, Secretary of.

O.—Mr. J. Oldfield, Lond.; Dr. James Oliver, Lond.; Mr. J. Offord, Lond.

P.—Mr. J. Pond, Norwich; Messrs. Parke, Davis, and Co., Lond.; Mr. Y. J. Pentland, Edinburgh; Plumbers' Company, Clerk of; A P. V., Worcestershire; Mr. Herbert Page, Lond.; Dr. A. H. Pirie, Exminster.

R.—Dr. Risien Russell, Lond.; Mr. O. D. Roe, Plaistow; Mr. R. B. Roe, Berae, India; Rochford Union, Southend-on-Sea; Rochdale Infirmary, Secretary of; Messrs. Reynolds and Branson, Leeds; Messrs. Reynell and Son, Lond.; Dr. A. Roche, Dublin; Royal Meteorological Society, Assistant Secretary of; Messrs. G. Reiss and Co., Manchester.

S.—Dr. G. C. Simmons Sacramento, U.S A.; Sheffield Royal Hospital, Secretary of; Dr. S. W. Smith, Cheltenham; Subscriber, Lond.; Dr. R. Sisley, Lond.; Messrs G. Street and Co, Lond.; Mr. A. Stenhouse, Glasgow; Messrs. Sparkes, Treherne and Son, Lond.; South Coorg Medical Fund, Sidapur, India; Dr. W. H. Symons, Bath; Miss G. A. Stokes, Cheltenham; St. Peter's Hospital, Lond., Secretary of; Messrs. Street and Co., Lond.; Messrs. Spiers and Pond, Lond.; Stockport Infirmary, Secretary of; Messrs W. H. Smith and Sons, Manchester; Miss E. A. Smith, Shrewsbury.

T.—Mr. J. Thin, Edinburgh; Mr. E. T. Thring, Sydney, New South Wales; Messrs. C. Tayler and Co., Lond.; Dr. Aldren Turner, Felixstowe; Taunton and Somerset Hospital, Taunton, Hon. Secretary of.

V.—Dr. A. Vost, Alva; Mr. J. W. Vickers, Lond.

W.—Mr. W. F. B. Weldon, Oxford; Mr. C. Webb, Margate; West Ham Hospital, Secretary of; Messrs. H. N. Warren and Co., Liverpool; Wakefield Medical Library, Hon. Secretary of; Messrs. Whitbread and Co., Lond.; Messrs. Wright, Dain, Peyton, and Co., Birmingham; *Western Clinical Recorder*, Ashfield, U.S.A.; Wolverhampton General Hospital, Secretary of; *Wilts County Mirror*, Salisbury.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. T. C. Angear, Chatham; Dr. J. R. Armstrong, Treorchy; A. E. D.; A. T. S., Lond.; A. C.; Aberdeen Royal Asylum, Treasurer of; A. R. M.; A. G.

Two Lectures

ON

RABIES:

Delivered at the University of London on Feb. 15th and 20th, 1900.

BY JOHN ROSE BRADFORD, M.D., D.Sc., F.R.C.P. LOND., F.R.S.,

PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTION; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.

LECTURE I.

Delivered on Feb. 15th

GENTLEMEN,—The work of the Brown Institution at the present time is divisible into three main classes. First, there is the hospital side of the institution, under the charge of the veterinary officers, thanks to whom a large number of animals are seen daily and treated either as in-patients or out-patients.[1] Secondly, there is the routine investigation of cases of suspected rabies which takes place in the laboratory of the institution and which has taken place there for the last five years. Previously to that period such cases were only sent there irregularly. Thirdly, there is the research work bearing on the diseases of animals and of man which is conducted in the laboratory either by the professor or by other workers.

In the five lectures which I propose to give in accordance with the provisions of the will of the founder it is my intention to deal in the first two with certain questions in relation to rabies, and in the last three with certain research work on the tsetse fly disease of South Africa. During the last five years a large number of cases of suspected rabies have been investigated—between 300 and 400—and a very considerable amount of information and material has been accumulated in that way. Most of this material is of very little use for the purposes of research, owing to a variety of circumstances which I need not go into, but as affording statistical material on the incidence and on the diagnosis of rabies the material is of considerable value. During the first three of the last five years all the cases of suspected rabies in this country were sent to the Brown Institution, but latterly the Board of Agriculture have undertaken the examination of cases of suspected rabies in their own laboratory, just in the same way as they investigate cases of other suspected diseases in animals, and so for the last 18 months the Brown Institution only has received the suspected cases in the area that is governed by the London County Council, and therefore the number has very considerably fallen off. I propose to discuss at some little length the question of the diagnosis of rabies, both in man and in animals. The term "rabies" is more suitable for the disease both in man and in animals than the term "hydrophobia," the latter term being to a very great extent, if not entirely, a misnomer. Before going into detail with reference to the more immediate subject of our lectures I will mention one or two general points in connexion with rabies, beginning with certain historical matters.

Rabies is a very remarkable disease and affords one of the most interesting examples of the progress of scientific investigation and of the way in which scientific investigation of a disease in a laboratory in a comparatively few years has thrown a flood of light on the nature of the disease under consideration. There are very few, if any, maladies which resemble it at all closely—tetanus perhaps resembling it more than any other; but rabies is, as you will see, a disease that is really very remarkable, more especially as regards its pathology.

We find that rabies is mentioned in quite early times—i.e., by Aristotle. It was not, I believe, mentioned by Hippocrates, but a very fairly accurate description of it is given by Celsus. Subsequently to that time, in the Middle Ages, there is very little mention made of rabies, and it is not until we come to the latter end of the last century that we find any accurate description of the disease. There is a certain amount of interest in the fact that it was very fully described by a very celebrated English physician—viz., Dr. Mead—in the year 1767, but from the time of Celsus to the time of Dr. Mead there is, I believe, very little mention in literature of rabies. Van Swieten in 1771 gave a very good description of the disease and this is of special interest in connexion with some of the controversies that have occurred in the last ten years, more especially with reference to the work of Pasteur. It is of interest to remember that Van Swieten recognised that there were two forms of the disease—a furious form and a paralytic form. So that more than 100 years ago the paralytic form of rabies was recognised and described. Of course, it was not then described as fully as we know it now, but it was definitely recognised, and that is a point of very great interest when we remember that a few years ago—I think in 1885—when a well-known case of paralytic rabies occurred in the human subject it was asserted by many persons, well-intentioned, no doubt, that it was a new disease which had been produced by Pasteur's methods, and that it was not a disease that was known to the older writers. Morgagni, the celebrated Italian observer, described rabies, and he fell into an error—an error which persisted until quite recent times and which persists still to a certain extent in the public mind. He fell into the error of believing that the disease was not, so to say, a specific disease, and he taught that it could be not only communicated by the bite of rabid animals but that it could also be communicated by the bite of animals which were not rabid but which were furious or enraged in the ordinary sense of the word and which were not suffering from the malady of hydrophobia or rabies. From the time of Morgagni onwards there is no observer whose work on the subject need detain us until the year 1811. Then a French observer, Gohier, made a considerable number of observations on rabies, and he was one of the earliest, if not the earliest, to experiment on rabies in the laboratory. Many of his observations have stood the test of time, but one of his facts—or rather one of his supposed facts—I think has not stood that test. He thought that the carcass of the animal was highly infective and that the disease was spread in that manner. Subsequently to 1811 we come to Gruner who in 1813 made important observations and I believe he was the first to determine the fact that the saliva was infective. That, perhaps, is the most important observation that was made from the time of Van Swieten. Van Swieten's observations, recognising that the disease existed in two forms, was a very important one, and Gruner's observation that the saliva was infective was similarly a most important one. The next observer who worked extensively at the subject was Berndt, whose work was published in 1822, and who confirmed the observations of others and who corroborated the original observations of Van Swieten that the disease existed in two forms—a furious form and a tranquil form. I believe he was the first to use these terms, the tranquil form now being usually spoken of as "dumb rabies." That brings us to the year 1822. The next most important observation was that of Galtier in 1871, who described the disease in rabbits. Inasmuch as the disease in rabbits is totally different in its main symptoms to that in dogs, the recognition of it in the rabbit and the description of the typical symptoms in that animal was a very distinct advance. In recent times the most important observations up to the time of Pasteur were those of Nocard and Paul Bert in 1880. These observers showed that if the saliva was filtered through plaster the virus remained on the plaster; in other words, they showed that the poison of rabies—the exact nature of which we do not know even at the present time—was a particulate virus.

Then we come to the work of Pasteur. In five years—and that was about the time that Pasteur's work on rabies extended over—in speaking of Pasteur I, of course, mean the work of Pasteur and his pupils—the additions to our knowledge of rabies were far greater than those of all other observers put together. That affords an illustration of what I said a few minutes ago, that rabies is perhaps the most striking instance of a few years' experimental work in the laboratory adding more to our knowledge than, I was going to say, centuries of accurate and careful observation. Pasteur's most striking and important discoveries in connexion with rabies may be said to be four in number. He demonstrated first of all that the virus was not only in the saliva but that it was also in the nervous system. That was the first fact which Pasteur and his pupils showed, and they proved that not only was the virus present in the central nervous system but that it was present also in the peripheral nervous system. It had been suggested—I ot know when, but some considerable time ago—that was so in the case of tetanus, and long before the terial origin of tetanus was known it was surmised t the poison of tetanus travelled by the nerves. In the ler surgical writings observations are recorded with reference to the part played by the irritation of small nerves in ounds as a cause of tetanus. It is in rabies, and as a result f Pasteur's work, that we have our best instance of the poison of a fatal disease producing its effects by acting on the nervous system, and not only producing its effects by this means, but apparently reaching the central nervous system by travelling along the peripheral nervous system. The foundation for that view of the pathology of rabies was laid by Pasteur's discovery that the poison was found in the central nervous system and also in the peripheral nervous system.

Pasteur's second discovery was the ease with which the disease could be directly inoculated provided that it was inoculated in the nervous system. A great many observers had previously tried to inoculate rabies. Some had succeeded and some had failed; and the fact that they used the subcutaneous method of inoculation or the method of simply rubbing the virus on a raw surface in the skin is the probable explanation of the very great difference in the recorded facts. Some observers had even gone so far as to say that the saliva was not infective; others found that the saliva was infective; others found certain organs to be infective and not other organs. There were great discrepancies largely dependent on the fact that the method of inoculation, as we shall see later, was not quite a satisfactory one. Pasteur added very greatly to our knowledge by showing that the inoculation into the nervous system was the best way of communicating rabies for experimental purposes from one animal to another; and the method which Pasteur invented and elaborated with reference to rabies has, of course since his time, been used, not only with so much success in the case of rabies but with certain success in the study of the pathology of other diseases. Both those facts Pasteur observed in 1881. Thirdly, in 1884 he made his first attempts, or at any rate he got his first results in his attempts, at attenuating the virus. He proceeded first of all on the lines he had pursued in studying similar problems in other diseases—viz., by seeing the effects of inoculating a series of animals of different species. After trying a large number of animals Pasteur found that if a succession of monkeys were inoculated the virus became attenuated, and finally, after passing through a considerable number of monkeys, that the poison did not produce such marked effects on dogs as it had originally produced. Conversely he found that by passing the virus through a series of rabbits it was increased in potency. But he very soon came to the conclusion that he could not hope to get curative effects or to elaborate any means of treating the disease by the results obtained in monkeys. Lastly, in 1885, he elaborated the very remarkable method which goes by his name for treating the malady, or more especially for preventing the malady in animals and in man. I do not propose to discuss that at any length; but you will remember that it consists in getting a virus of a certain fixed strength which he called "*le virus fixe*," and this he obtained by passing the disease through a succession of rabbits—I think about 100—until the period of duration of the disease and the period of incubation of the disease are both absolutely fixed. It is well known that if you take the sporadic cases of rabies which occur in the streets sometimes the virus from one dog will produce a malady with a short incubation period, and the disease will run a rapid course, while in another case it will have a long incubation period and may run a very much slower course. Pasteur thought that it was essential to work with a virus of constant strength and he obtained this virus of constant strength by passing it through a succession of rabbits. Having done that he found that the virus was attenuated by drying, so that if the spinal cord of the rabbit be removed and dried he found that in the course of a fortnight the virus had completely lost its strength. Those who have seen Pasteur's Institute may remember the darkened room which is kept at an equable temperature, in which the spinal cords of these rabbits are dried. Therefore, by preparing separate extracts of these spinal cords every day extending over a period of a fortnight a virus of different degrees of potency could be nd that forms the basis of his method of treating thod I do not propose to discuss now.

Since 1885 our knowledge of the nature of rabies has not really greatly progressed. A number of observers have recorded that they have isolated an organism in cases of rabies, but at the present time there is no consensus of opinion amongst bacteriologists with reference to this question. I think it cannot be said that the identity of the organisms of rabies has been clearly established, although, of course, there are many strong arguments in favour of the disease being of microbic origin, quite apart from the observation of Nocard and Paul Bert which I have mentioned, that filtration of the saliva through plaster removed the virus.

That is a very short historical sketch of the progress of a portion of our knowledge with reference to the nature of rabies. There is one other point which one would like to go into before dealing with the immediate question of diagnosis, because one cannot really discuss the diagnosis without first discussing this. I refer to the question of the animals that are liable to be affected by the disease.

Rabies, as you know, is a disease which is common to man and to animals, but all animals are not affected with equal ease nor does the disease run the same course in all animals. It affects all the mammalia and it also affects birds, but it is very doubtful whether it affects the amphibia. It is said by one observer to do so, but others have been unable to confirm his observations. So we may say that the disease is limited to the mammalia and to birds. As a matter of fact, in the case of birds it is mainly seen as the result of experimentation. It is very difficult, as would occur to anyone, for a bird to be inoculated from a bite for obvious reasons; amongst other reasons is the fact that the feathers would probably remove the virus, so that the question of the disease affecting birds is not one of any great practical importance, although there is a considerable degree of theoretical interest about it, because birds are more refractory to rabies than are mammals. In mammals, as you know, the carnivora are those which are especially affected, and you know also that it is a disease which affects not only domestic animals but also wild animals. Some of the most serious outbreaks of rabies, both in animals and in the human subject, have occurred owing to its prevalence in wild animals. As regards wild animals, those of most importance from our point of view are wolves and foxes. Wolves, of course, have been a frequent source of rabies, both in France and in Russia, more especially in Russia, and it is not uncommon, I think, for outbreaks of the disease in this country to be associated with its prevalence in foxes. As regards other animals, the disease is not uncommon in cattle and it is more common in horned cattle. It is more common in cattle than in goats. It is not very rare in horses, but it is much rarer in horses than in cattle. It is exceedingly rare in pigs. A suggested and a probable explanation of this fact is that there is a very large amount of subcutaneous fatty tissue in the pig, and, as we shall see later, subcutaneous fat is not at all suitable for the inoculation of rabies. Therefore, the disease is common in dogs and cats, not uncommon in wolves and foxes, but in other animals it is rare—most rare in the pig, less rare in the horse, and least rare in cattle.

Another interesting point in reference to rabies is that, like many other diseases, perhaps nearly all diseases, it exists in certain localities and is very difficult to eradicate from those localities. Then at intervals of longer or shorter duration there are epidemics of rabies. In this country, for instance, Lancashire has long had an evil repute as a district where rabies is more or less endemic, and the same is true of Ireland and of certain districts in Germany and France. As regards epidemics, there was a very severe epidemic indeed in France and in Germany, and, in fact, in the whole of the western side of Europe, in the years from 1720 to 1723. In this country the best known epidemics of rabies—of course, I am speaking of rabies in animals—were from 1754 to 1762. There was a very severe epidemic in Lancashire in 1864. Then, more recently, there was what I think I may call a severe epidemic in the year 1894–96, and in 1895 and 1896 there was a very considerable amount of rabies in London. In 1897 there was not so much, in 1898 still less, and this last year I think I am correct in saying that there were no cases of rabies, anyhow none came under my observation. There have been epidemics amongst dogs an cats, but in addition to that in this country there have bee severe epidemics amongst deer. The most interesting ar extensive epidemics amongst deer have been these. In 17 there was an attack of rabies amongst the deer in the Ro parks, then there was a severe epidemic in 1872 in he of deer belonging to the Duke of Westminster, and it will be within the recollection of most of you that there was a very severe epidemic in 1886 among the deer in Richmond Park, where amongst 1200 animals 264 were affected with rabies. Those are the principal epidemics of the disease which have occurred in this country in recent times.

There are certain countries in which rabies is unknown, and amongst these countries are Australia and Norway. There are other countries where outbreaks of rabies have occurred as the result of the importation of dogs, and, it is said, more especially of sporting dogs. There is an impression that is very current that rabies is a malady which is especially apt to occur amongst uncared for dogs, whereas that is not at all the true state of affairs. Rabies is a disease which may occur in any dog, and we are always struck with the considerable number of cases in what are commonly called sporting dogs which are sent to us for diagnosis. There are three epidemics which have been laid to the charge of sporting dogs taken from this country. One of these was in the Mauritius in 1813, one was in Malta in 1847, and one was at Shanghai in 1867.

How is the malady communicated? In the great bulk of cases it is communicated by bites, and that is one of the very reasons why the prevalence of it amongst the carnivora is so important for us to recognise. When it is communicated by a bite you know that, on the whole, the cat is the more dangerous animal, owing to the fact that the cat is liable to "fly," as it is said, to the more exposed part of the body—the face, for instance—and also, perhaps, owing to the fact that it is well known that bites in the face, for reasons we will consider later, are more dangerous than bites in other parts of the body Rabies, perhaps, can also be communicated by licking—that is to say, by licking a raw surface on the body. But it must be always remembered that the virus of rabies is not one that is very easily inoculated, and that it is much more difficult in the laboratory to communicate rabies by smearing a raw surface with the saliva than it is by injecting it hypodermically. It is more difficult to communicate it hypodermically than by injection into the muscles, and it is more difficult to communicate it by injecting it into the muscles than by injecting it into the eye. Further, it is more difficult to communicate it by injection into the eye than by introducing it subdurally. So that I do not know that it can be said that it has been accurately proved that it can be communicated by licking, but at any rate it is probable. It is said that when people are bitten by a rabid animal from 10 to 20 per cent. of the sufferers succumb to rabies. That is a matter on which it is most difficult to get statistics. Anyone who has had occasion to look the matter up will find very varying statements with reference to this point Apparently, however, the balance of evidence is in favour of that view. A French observer, Leblanc, who collected a great number of accurate statistics—accurate, that is, as far as one can see—stated that the percentage was about 16. There is a very celebrated case quoted by Hunter where one mad dog bit 21 people and only one person succumbed from the disease. That has been sometimes quoted as showing that the mortality of the disease is only 5 per cent, but of course that is erroneous. The disease can also be communicated by infection at post-mortem examinations; and there have been instances of that amongst veterinarians. I am not aware of any recorded instance of such infection by the human subject—I mean of a human being having been infected by doing a post-mortem examination on a case of rabies in man—but there are cases on record in which it has occurred to veterinary surgeons. The third way in which it is said to be communicated is by the ingestion by animals of the flesh of other animals which have died from the disease. Here, again, there has been great controversy, many observers having failed to communicate the disease in that way and others having succeeded. Of course, an obvious explanation occurs—viz, that the question as to whether an animal contracts rabies or not by eating the flesh of an animal dying from rabies is whether there is any lesion in the throat or alimentary canal or not. Fourthly, it has been shown that it can be communicated by the milk of a suckling animal or of a suckling human being. There is a case recorded in the West Indies where an infant was suckled by its mother who was suffering from the early stages of rabies and the child contracted the disease and died from it before the mother. It has been proved in the laboratory that the milk of suckling animals, and human milk in cases of rabies in woman, is infective. Still, that is a point of only scientific interest.

Lastly, it has been shown in the laboratory that it can be communicated through the mucous membranes. The French observer, Galtier, has shown that if the virus of rabies be put into the conjunctival sac or into the interior of the nose a certain proportion of the animals so treated will succumb to rabies. These are really only matters of scientific interest. For all practical purposes the disease is communicated by biting, and you know that the danger of a bite depends very largely upon the part of the body upon which it is situated, quite apart from the question of clothes. Of course, it is obvious that bites in the legs and in the feet are less dangerous than bites in the hand or face, owing to the probability of the saliva being wiped off by the clothes or the boots. But, apart from that, there is, apparently, evidence that the inoculation of the virus into the face, for instance, is more liable to be followed by a rapid onset of the disease than if it is inoculated in the legs. The well-known experiment of Roux in which an animal was taken, the spinal cord was divided, and then the virus of rabies was inoculated into the hinder portion of the animal, throws some light on this question. Under those circumstances it can be shown that the lower segment of the spinal cord, separated from the central nervous system, will contain the virus in great quantity and in a high degree of virulence at the time when the upper segment does not contain it. And so it has been thought that the proximity of a part to the central nervous system does play a part and is a point of importance both in the progress and in the rate of onset of the malady. So that a wound of the face, inasmuch as it is near the central nervous system, is for that reason more dangerous. There are one or two other general points which I may mention.

First of all, let me say a few words with reference to the virus. I have already said—perhaps more than once—that rabies is a remarkable disease; but there is nothing, perhaps, in which it is more remarkable than in the nature and in the situation of the virus. We have seen that the virus is present in the saliva. We have also seen that it is present in the central nervous system and in the peripheral nervous system, but that it is not present in the blood. All observers are agreed that the blood of animals suffering from rabies is not infective. It is apparently not present in the bulk of the tissues and organs of the animal. It is not present in the muscles. It is not present in the liver or the spleen. It is present in the glands, such as the salivary glands, the pancreas, the lacrymal gland, the suprarenals, and the mammary gland; and it has always seemed to me, since I have been working at the subject, that that is one of the most striking phenomena in pathology—that this potent virus should be present in the central nervous system and in the secreting glands but should be absent from the blood and from the tissues such as those of the liver and the spleen. It is present, as I mentioned a minute ago, in the milk of suckling women; it is not present in the urine. It is said to be present in the seminal fluid, but in this there have been discrepancies among different observers. However, there have been no discrepancies as regards the saliva and those glands I have mentioned nor as regards the milk. Then, as I mentioned a few minutes ago, the virus is slowly destroyed by being dried in the air; and it takes about a fortnight for it to lose its virulence under those circumstances. When exposed to the air and to sunlight it loses its virulence in about 14 hours. In water it will maintain its virulence for as long as 40 days—for from 20 to 40 days—and in glycerine (which is a point of some importance with reference to the techn[illegible] of inoculation) it will maintain its virulence for a[illegible] as a month. Then an important point where one [illegible] to investigate suspected cases of rabies is the influence of putrefaction on it. It has been found by French observers that the virus remains potent in the carcass of a dog which has been buried for 44 days; it has been found potent in that of a rabbit 27 days after burial and in that of a sheep 21 days after. So we have periods ranging from three to six weeks. My own experience does not quite agree with this I know that I have failed twice to detect the presence of rabies in an animal which undoubtedly died from the disease where the carcass of the dog had been buried only a few days and had then been exhumed and sent to me. In one of those cases—a case in which a man had been bitten by the dog in the ear and had died from hydrophobia, so that one had very clear evidence quite apart from the suggested diagnosis of rabies from the symptoms in the dog—the inoculations from that dog were quite ineffective. That was probably owing to the presence of putrefaction. It occurred in the hot summer months. But the French observers—and that is the only discrepancy between their results and such results as I have obtained—have always laid stress on the point that ordinary putrefaction does not prevent the recognition of the presence of rabies in a buried carcass. Of course, you may often fail to detect the presence of rabies in suspected cases if there happen to be other organisms present, especially organisms capable of causing septicæmia, owing to the obvious fact that septicæmia runs a more acute course than rabies, and so perhaps both diseases may be communicated, but the animal dies from septicæmia before the symptoms of rabies have become manifest.

The only other point I wish to mention before discussing the diagnosis in full is the question of incubation. The diagnosis very often turns on incubation. The incubation period of rabies is known to vary greatly in different animals. I have prepared here a list of the more important. Most observers are agreed now that in man the incubation period of rabies lies between 20 days as a minimum and 60 days as a maximum and that it is rare after three months and very rare, if not unknown, after six months. One is perfectly aware of cases that have been mentioned in which the disease is said to have occurred after as long a period as 18 months, but I believe that the modern work on the subject has rather tended to the belief that there must be some error in those cases. But it is the minimum period which is of importance, because, as we shall see later, one of the important points in the diagnosis in the human subject is to distinguish rabies from a functional disturbance simulating rabies, which has been called by some observers "lyssophobia," and one of the points on which great stress is laid is the incubation period. It is of some importance to recognise that the disease in the human subject does not occur at a less period than 20 days after the bite. In a dog the incubation period is from 15 to 60 days and at least half the cases in the dog occur in less than a month after the bite or after exposure to contact with an animal suffering from rabies. In other animals the incubation period, from the point of view of practical medicine, is not of very great importance. In cattle it varies from one to three months; in sheep from 15 to 30 days; and in the horse from 15 to 60 days. Therefore, if you eliminate cattle, you may say that the incubation period in most animals varies from 15 to 60 days.

Now to come to what I propose to deal with in detail in my next lecture—diagnosis—I will only say now that the diagnosis of rabies can be considered from three points of view. You have, firstly, the clinical diagnosis, which is on the whole the most important, but it is not always the diagnosis which one can make, though it is the one which it is most desirable to make, especially in the case of an animal, owing to the loss of time that must necessarily occur if the diagnosis be made by any other method. Secondly, there is the diagnosis by post-mortem examination. Thirdly, there is the diagnosis to be made by experimental means. Now it is a very obvious thing, but it is sometimes forgotten, that the clinical diagnosis, especially in animals, is most readily arrived at by the question of the period of survival after the onset of the symptoms. This is a matter which I have mentioned here before and I will do so again. If a dog which is suspected of rabies bites an individual, that individual is, of course, most anxious to know whether the dog has or has not got [illegible]. It is a matter of the most vital importance to [illegible] a matter of life and death. If that dog be killed, [illegible] probably the case in 99 cases out of 100, the [illegible] a interval of three weeks at least must elapse before it can be stated positively whether the dog had or had not had rabies. On the other hand, if the suspected dog be isolated the question can probably be answered with certainty in from two to four days, so that the clinical diagnosis of rabies, the diagnosis in the living animal, is a matter of very great importance. The tendency nowadays is rather to rely on the experimental method. I should be the last to decry the value of that method, and it may be the only means by which you can say that the dog has or has not got rabies, but in many cases very valuable time is lost by killing the animal and investigating it experimentally. I think you will at once see how, if the animal be killed, it may be impossible to diagnose the disease in a shorter period than three weeks. It is for this reason—that the post-mortem signs of rabies, both in the human subject and in animals, are not very marked. They are at the best rather equivocal signs, especially in animals, and, further, the most characteristic post mortem signs of rabies in the dog are not developed until the malady has been allowed to run its full course. If the animal be killed on the very first day after it has become strange in its behaviour the post-mortem examination may be absolutely negative; it may show that the dog is apparently perfectly well. That is clearly a very serious fallacy. Therefore, the clinical diagnosis of the disease is a matter of the greatest importance. The difficulty of clinically diagnosing the disease in the dog lies first of all in the difficulty owing to the symptoms, as rabies resembles other diseases in the dog, and, secondly, there is great danger in keeping a mad dog alive. If, however, the dog can be isolated so that it cannot do any harm it would be wiser to do that than to kill it, even if it has bitten anyone, because under those circumstances, in two or three days, perhaps less, you will have very strong presumptive evidence of the existence of rabies, simply by the death of the animal with the characteristic symptoms of that disease.

In my next lecture I will consider the details of the diagnosis, both clinically and by post mortem examination, as well as the diagnosis by the experimental method, and I will more especially deal with the fallacies that are liable to occur in the experimental method.

The Arris and Gale Lectures

ON

THE ANATOMY AND PATHOLOGY OF THE RARER FORMS OF HERNIA.

Delivered at the Royal College of Surgeons of England on Feb. 19th, 21st, and 23rd, 1900,

BY B. G. A. MOYNIHAN, M.S. LOND.,
F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY, CONSULTING SURGEON TO THE SKIPTON AND DISTRICT HOSPITAL, ETC.

LECTURE III.[1]

Delivered on Feb. 23rd.

HERNIA OF THE BLADDER.

MR. VICE-PRESIDENT AND GENTLEMEN,—Hernia of the bladder is still regarded as a surgical curiosity. During the last decade the number of recorded cases has been steadily increasing. Up to the present time approximately 200 cases have been recorded. Of these only 38 were observed before the year 1890. In 1890 it may be supposed that Bassini's operation began to assert its claim to be considered as one of the most successful of the methods for the radical cure of inguinal hernia. One of the features of this operation is the necessity it imposes upon the surgeon of opening up the inguinal canal and exposing to view that portion of the sac, one and a-half inches or less in length, which lies between the internal and external abdominal rings. If a small process of the bladder lay externally in contact with, or internally as a content of, the sac, it would inevitably be exposed, if not at the moment accurately observed or appreciated, during this procedure. An examination of all the published cases elicits a fact of some interest in this regard. All the earlier cases contained a very large amount of the bladder; some of them, verified by post-mortem examination, contained the whole bladder, including in at least two cases the prostate also. It is more than likely that any small or medium-sized hernia containing probably only a very insignificant portion of the bladder, would pass unrecognised in the days when a hernia, unless strangled, was seldom or never submitted to operation.

DEFINITION.

Hernia of the bladder may be defined as the appearance of the bladder at any of the usual hernial orifices, whether in relation with the peritoneum or not This definition, though not scientifically exact, will probably best meet the exigencies of the case Strictly speaking, an abdominal "hernia" cannot exist without a sac; but as the clinical manifestations of a case of bladder hernia without sac are to all intents indistinguishable from those where the sac is partial or complete no good purpose could be served by separating, for academic purposes, the descriptions of the several conditions.

---

[1] Lectures I. and II. were published in THE LANCET of Feb. 24th, 1900.

HISTORY.

It is generally stated, upon the authority of T. Bartolin, that the first case of hernia of the bladder was recorded in 1520 by G D Sala In Verdier's monograph to be subsequently referred to, this statement is repeated in a quotation from Gunz *Giovanni Domenico Sala Professor of Medicine* at Padua, lived from 1579 to 1644 Thomas Bartolin lived from 1616 to 1680; in his 'Histor Anatomic, centur IV, hist 28," he remarks, giving no date, that a case of bladder hernia had been observed in Venice by Sala, "Preceptor olim et amicus noster" The date 1520 is therefore, without doubt, a misprint for 1620 The first person to record a case of hernia of this variety was Felix Plater, of Basle, who lived from 1536 to 1614 No date is given on the original, but Verdier fixes the date at 1550 The classic account of this disease was written by Verdier in 1753 From that year up to 1890 *practically no observations of any importance* were recorded Isolated cases of greater or less interest were recorded by Percival Pott (who removed a stone from an inguinal cystocele), John Hunter (a specimen, "Hunterian," of inguinal cystocele in a lion is in the Museum of the Royal College of Surgeons of England), Astley Cooper, and others In the last few years papers of importance have been written by Legard, Anslun, Lotheissen, Brunner, Berger, Jaboulay, Monod and Delagenière, and Sjövall.

FREQUENCY.

Inguinal hernia, much more frequently than crural, contains the bladder It is difficult to gauge with even remote accuracy the percentage occurrence of cystocele. From recently published statistics I select the following list, for in each of these instances all the cases of hernia submitted to operation are enumerated without selection —

Lucas-Championnière	in 475	operations found	2	bladder hernias
Krönlein	„ 278	„	1	„ hernia
Bassini	„ 262	„	1	„ „
Hahn	„ 250	„	1	„ „
Corazza	„ 103	„	1	„ „
Mousri (Novaro's cases)	„ 283	„	6	„ hernias
Montegnacco	„ 260	„	4	„ „
Von Hacker	„ 702	„	7	„ „
Total	2613 cases		23	bladder hernias

This would give, roughly, 1 per cent. of cystocele

Sealistschew, writing in 1897 gave the percentage as 5 88 One fact, which many surgeons attest, is worthy of remark A very large number of cases of hernia may be submitted to the operation for the radical cure without any case of bladder implication being observed Then, unexpectedly, during an operation a portion of the bladder, recognised and duly attested, is seen In subsequent operations special attention is paid to the point, and a careful search is made for any evidence of involvement of the bladder Consequent upon this several similar cases are noticed The rarity of recorded examples is due, it would seem rather to a want of pertinent observation than to the infrequent existence of the cases That a more intimate examination of the neck of the sac and of that portion of the sac lying within the abdominal wall results in the discovery of small bladder pouches is shown by the cases recorded prior to, and subsequent to, the introduction of Bassini's operation In the Innsbruck clinic 455 cases were operated upon by Von Hacker before a cystocele was observed After the occurrence of this case instruction was given that in all operations special emphasis was to be laid upon an examination of the neck of the sac In the next 187 cases operated upon by Bassini's method six cystoceles were laid bare In 60 cases of Kocher's operation no evidence of bladder descent was noticed By Kocher's method it would be almost impossible to recognise a cystocele limited to the inguinal canal The conclusion would seem to be inevitable that, as Lotheissen says, "the more exact the stripping of the sac, quite up to the deep epigastric artery, the more likely will cystocele especially in its earlier stages, be discovered"

Broadly speaking, it may be affirmed that hernia of the bladder is a disease of the aged and enfeebled Four cases only of inguinal cystocele have been recorded in children The first was recorded by Percival Pott in a child six years old The hernia was supposed to be a "tumour" and was incised; it was recognised as the bladder when a calculus was removed The second was recorded by Wyeth in a child, two and a half years old, with incarcerated hernia, the bladder was incised and stitched; a good recovery followed. The third was recorded by Kummer in a child five years old It was an omental hernia, recurring one year after a radical cure The fourth was recorded by Lotheissen in a boy 11 years old The average age of the males in all published cases was 51 years and of the females 44 years The majority of the cases occur between the ages of 50 and 60 years *The relative frequency on the right and left sides is* as 1 46 to 1 (Sjövall)

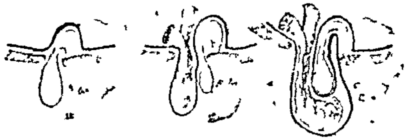
The following table arranged after the fashion of Brunner's, gives all the recorded cases I have found:—

Men 134	Inguinal 118	Right	61
		Left	41
		Double	4
		Not mentioned	11
	Crural 2	Right	1
		Left	1
	Perineal		2
	Other forms		2
Women 45	Inguinal 11	Right	3
		Left	6
		Double	1
		Not mentioned	1
	Crural 27	Right	22
		Left	5
	Perineal		4
	Other forms		3
Sex not stated 9	Inguinal		6
	Perineal		2
	Other forms		1

VARIETIES OF CYSTOCELE

There are three distinct forms of cystocele which may be most aptly described after the manner of Jaboulay and Villard as: (1) intra-peritoneal (Fig 11 *c*), (2) para-peritoneal (Fig 11 *b*), and (3) extra-peritoneal (Fig, 11 *a*)

FIG. 11.



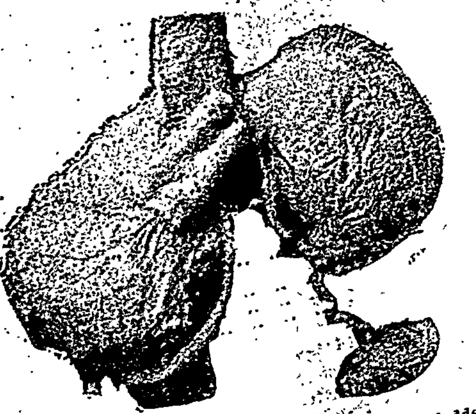
The three varieties of cystocele A Extra-peritoneal. B Para-peritoneal C. Intra peritoneal.

1 *Intra-peritoneal cystocele* (*Tumeur herniaire avec intussusception de la vessie* Duret · *Hernie par bascule*)— In this variety the conditions are as follows There is a complete hernial sac occupying the position of an oblique inguinal hernia, the neck of the sac, that is to say, is external to the deep epigastric artery. Into this sac a portion of the bladder *completely covered by peritoneum* descends That portion of the bladder implicated in the hernia is the upper part of the posterior surface This form of hernia is rare According to Lotheissen, probably only about 6 per cent of all cases of cystocele are of the intra peritoneal form. This estimate seems to me to be in excess of the truth Out of nearly 200 cases I can only discover four of the inguinal variety and one of the femoral (Gibson) in which the description leaves no doubt as to the exact nature of the hernia The hernia in all cases was very large and the hernial rings widely dilated It is always *secondary* in origin The sac may contain the bladder only or bladder with intestine or omentum On tracing the peritoneum of the inner wall of the sac inside the abdomen it is found to sweep round a little distance inside the internal abdominal ring in order to become continuous with that which clothes the bladder The viscus must therefore be twisted round on its vertical axis, a fact which is recognised by the description "*hernie par bascule*" of Leroux and others

2 *Para peritoneal cystocele* (Fig 12) (*Tumeur herniaire avec adossement de la vessie*)—In this form there is a hernial sac, either of the oblique or direct form On the inner side of the sac lies the bladder, in such manner that the peritoneum of the inner wall of the sac is the serous

covering of the outer wall of the bladder. The rest of the bladder outside the abdomen has no peritoneal covering. The viscus, therefore, is outside the sac; it is not a part of the contents of the hernia. The hernial sac may contain intestines, large or small omentum (Guterbock, Sorel, Berger), ovary (Guinard), or tube and ovary (Lejars, Reymond), or it may be found empty. This variety forms, according to Lotheissen, about 24 per cent. of all recorded cases. The estimate is probably far below the truth. Since accurate and exact records have been kept of these cases the proportion has been considerably greater. Sjövall gives 40 per cent. as correct, but even this is probably too small. In not a few cases believed at first to be extra-peritoneal a further and more careful examination has revealed a small and inconspicuous peritoneal descent on the outer side of the bladder. The relative size of peritoneal sac and bladder implicated in the hernia varies within considerable limits. On the one hand, the sac may be large and capacious and a mere fringe of bladder be present in the canal, or, on the other hand, the bladder involved may be large and bulky and the peritoneal descent quite trivial and inconspicuous. In about one half of the total cases, 51 per cent. (Sjövall), the bladder has been thickly covered with fat. When the sac has been stripped up after the reduction of its contents a thickening, more or less massive, of the upper and inner portion has been discovered. This thickening has been looked upon as a lipoma, a second sac, a cyst in connexion with the sac, or as mere indeterminate thickening. In two cases at least the position of the bladder was different from that which I have described. In one, an inguinal hernia, the relation of the bladder is thus described: "Outside the sac and lying external to it and slightly below it" a long process was found which on examination revealed the bladder. In a femoral hernia the bladder is described as lying "on the outer side."

FIG. 12.



Vesical hernia. Sir Astley Cooper's case. The bladder is covered by peritoneum except at the inner and posterior part. Para-peritoneal form. (Guy's Hospital Museum, No. 1170.)

3. *Extra-peritoneal cystocele.* (*Cystocele sans sac sereux, Duret.*)—This is a rare form. As has been mentioned, some cases apparently of this variety prove on examination to be "para-peritoneal." According to Brunner only six cases have been confirmed by post-mortem examination. It seems open to question whether any case of this form should be definitely accepted without the evidence of a careful dissection. The small peritoneal diverticulum converting an "extra-peritoneal" into a "para-peritoneal" example may be quite insignificant. Of the six cases four were of the inguinal variety and two were femoral. As a general rule the hernia is very small, of the size of a walnut or thereabouts. The largest tumour was "of the size of an orange." All extra-peritoneal herniæ are of the "direct" variety.

Of the three forms, then, the para-peritoneal is, beyond all question, the most frequent. It includes the smallest as well as the largest herniæ. The amount of the bladder engaged, too, in the hernia varies between the two extremes. In some cases, either para-peritoneal or extra-peritoneal, the merest "pinch" of the viscus may lie in the inguinal canal. In others, notably in one recorded and figured by Kronlein, the whole bladder, with the prostate, portions of both ureters and the vesiculæ, with the terminal portions of the vasa deferentia, may lie outside the abdomen. It is incidentally worth remark that Reichel has described as "inguinal hernia" which contained only a small dilated portion of the ureter on the right side. The bladder wall engaged in the hernia is, in about half the recorded cases, covered with fat—sometimes densely so. There is occasionally a slight thickening of the bladder, but more frequently there is thinning. To such an extent may this occur that the wall appears no thicker than the serous membrane over it. In a few cases the bladder has been recognised by the presence of muscular fibres.

On reading through the reports of cases one is struck by the constant repetition of the phrase "diverticulum" of the bladder. The pouch-like protrusion is said to be connected with the larger intra-pelvic portion of the bladder by a narrow neck. Percival Pott describes the size of the connecting channel in his case as "about the breadth of the largest wheat straw." Recent investigations, however, certainly tend to show that, speaking accurately, no diverticulum ever exists. A certain appearance of narrowing may be seen at the internal abdominal ring as a result of constriction there, but all that portion of the viscus contained in the canal or scrotum is nevertheless bladder, more or less altered and attenuated. So narrow may the neck of the sac be that urine finding its way in from an over-distended bladder is with difficulty returned. Inflammatory process may then develop and the urine retained undergoes decomposition. A phosphatic deposit on the walls may be thrown down, and to such a degree may this occur that a definite calculus may be formed. Stalpart van der Wiel makes mention of two cases in which inflammation resulted in abscess of the groin. On the abscesses bursting calculi were discharged. J. L. Petit records the case of a man, the subject of a vesical hernia, in whom it was possible to feel several small stones in the protruded viscus. The stones were small in size, could be made to pass to the intra-abdominal portion of the bladder, and eventually were voided with the urine. Gross, Percival Pott, and Imbert record similar examples.

Intra-peritoneal cystocele is always of the oblique form, para-peritoneal may be either oblique or direct, extra-peritoneal is direct. In addition to these forms of hernia of the bladder there are two other varieties which have been described by Hermes as "operative cystocele" (*cystocele opératoire*). In the first of these the bladder does not lie within the inguinal canal; but as a result of the stripping of the sac up to the internal abdominal ring and of the traction upon the sac before its transfixion a small tongue-shaped slip of the viscus is dragged down below the level of the internal abdominal ring. In such a condition the bladder may readily be pierced by the needle or included in the ligature. The more complete the stripping of the sac and the more vigorous the traction exerted the more likely is it that the bladder will be dragged downwards. In Bassini's and similar operations operative cystocele is therefore proportionally more frequent than in those procedures not involving a laying open of the canal. The second form of operative cystocele occurs in patients who have been subjected to the "radical cure" ineffectually (*cystocele post-opératoire*). The conditions of such a hernia are essentially different from those of the ordinary hernia and it is well to emphasise that difference by a separate classification.

ETIOLOGY.

The explanation of the existence of the bladder within a
hernial sac is a problem that has exercised the minds o
surgeons for over a couple of centuries. Felix Plater, wh
recorded the first example of this disease, was at a loss
understand how an organ usually so fixed in the true pel
could come to be outside the abdomen. Mery, who early
the last century recorded three cases, looked upon the her
as congenital in origin, and his view has been supported
Armands, Emmerts, and others. During the early year
life the bladder is an abdominal rather than a pelvic or
and any congenital defect would, one might t
be calculated rather to induce a hernia during
years than in later life when the bladder has s
in the pelvis. The number of bladder hernias re
in children (see above) is remarkably few

which
Urinar
and in

our cases being known. Investigations carried out by Eng-asch in 1877 suggest to him that an abnormal condition of be ligamenta vesico-umbilicalia lateralia, an ineffective or rregular development that is to say, may be responsible for he initial fault. The premature involution of the vessel ontained in this fold may lead to the formation of strong eritoneal folds which render the resistance to the backward listension of the bladder considerably greater than to the lateral. The bladder slowly widens out and reaches the internal abdominal ring more readily than under normal conditions. Peritoneal fossæ to the outer side of these folds are described by Waldeyer and Aschoff. Berger has remarked that "the predisposing causes of vesical hernia are those which lead to an increase in the capacity of the bladder and determine a thinning of its walls."

In order to permit of the engagement of the bladder in the internal abdominal ring the organ must have suffered some deviation from the normal. Its wall must in many cases have undergone such thinning as commonly results from frequent and long-continued over-distension. It is therefore probable, in the first place, that any disease or defect in the lower urinary tract would predispose to such pathological alteration. Stricture of the urethra, prostatic hypertrophy, with bladder atony, and the atony following acute cystitis, may be mentioned as not unlikely to cause the thinned, flaccid, degenerate bladder to approach the inguinal region. But prostatic hypertrophy is common, bladder hernia is rare, and although the association of the two is striking in its frequency it is natural to suppose that there are other factors at work.

It has already been mentioned that in cases of hernia of the bladder the viscus is more or less thickly covered with fat. This fact was, I believe, first noted by Verdier, and is also mentioned by Keate, "Cases of Hydrocele, with Observations on a Peculiar Method of Treating that Disease, to which are subjoined a Singular Case of Hernia Vesicæ Urinariæ, &c." This paper was published in London in 1788 and in it Keate remarks: "From the great abundance of fat all round the bladder it might be concluded that the fat had facilitated the descent of the bladder." Scarpa in his work remarks: "In another subject I found among the coverings of the testis a large quantity of fat, which extended up the cord through the canal and blended with the fat lying by the side of the bladder. When I pulled upon the fat between the testis and the neck of the sac I drew the bladder down so that at last it reached to the level of the testis." This "lipome pre-herniaire" has been accredited by Monod and Dalagenière with a considerable influence in the etiology of hernia of the bladder. "Occasionally soft, almost diffluent, this fat sometimes forms merely pellets of fat, at other times a thick stratum of fat which surrounds the bladder." An examination of a number of cases where the inguinal region and the pelvis may be considered normal reveals the following condition. Extending along the cord as it lies in the inguinal canal is, in the majority of cases, a certain amount of fat. Occasionally in small round granules, but more commonly in elongated strings, this fat is of a peculiar soft, succulent, oily, and homogeneous character. At the internal abdominal ring it turns inwards with the cord and is continuous with the fat surrounding the upper part of the bladder. Occasionally the fat is continuous with a more or less well-defined cord of fat extending upwards along the psoas muscle to the kidney. Lockwood has recently shown in his admirable little book on "Hernia, Hydrocele, &c.," that not a few cases diagnosed as inguinal hernia reveal, on the laying open of the inguinal canal, nothing more than a "lipoma of the spermatic cord," a condition, that is, in which the fat I am describing has undergone a considerable increase in bulk. A further interesting fact, to which both Andrewes and Lockwood have drawn attention, is that in this fat some remains of adrenal tissue have been found. In a case of my own a large lipoma extending from the scrotum up the cord, through the inguinal canal, filling the iliac fossa, and extending upwards almost to the pancreas, contained a fair number of epithelial cells in varying stages of degeneration. This fat, therefore, has, morphologically, a past, and clinically it probably has a future. An examination of the fat surrounding the bladder shows that it does not merely coat the wall, but that it insinuates itself to some degree between the muscle fibres themselves. Monod and Delagenière in a striking contribution to the study of this subject assert that the excessive development of this fat, its conversion into the "*lipome herniaire*," results in the fixing the bladder at or near the internal abdominal ring. Other causes, laxity of the abdominal wall, increase of intra-abdominal pressure from effort, and so forth, result in the forcible expulsion of the upper and outer portion of the viscus from the abdomen. Jaboulay, who confirms the experience of most surgeons as to the existence of this doughy cake of fat, considers that it acts not as a point of fixation, but that it favours the descent of the bladder "*par glissement*."

It has been generally overlooked that this supposed method of the formation of vesical hernia is nothing more than an old friend under a new name. German authors have for over a century considered the possibility of the formation of peritoneal sac by small masses of fat. The "Zug theorie" endeavours to explain the existence of hernial sacs by the dragging on the peritoneum by these small pellets of fat, local increases of the ordinary sub-peritoneal fatty tissue. Pelletan, who wrote in 1780, suggested that these fat nodules might induce the descent of a hernia. In these two conditions the over-distension due generally to prostatic diseases, with the associated loss of general muscular power, and the existence of the pre-vesical fat, we probably have the two chief factors which lead to the development of cystocele. In the various forms these factors do not, in all probability, act with equal effect. In extra-peritoneal cystocele are found distension of the bladder, feebleness of its muscular coat, strenuous efforts to empty the bladder, wasting, bulging, and laxity of the lower abdominal wall—the condition, in fact, which has been aptly and graphically described by Guyon under the term "prostatism." In para-peritoneal cystocele, as Jaboulay has pointed out, the hernia is generally voluminous. In such cases the cystocele is secondary and is due to the dragging down of, and further demands upon, the parietal peritoneum. If, on the other hand, the hernia is small, the sac quite inconsiderable and probably empty, while the bladder is of considerable bulk, densely hidden with fat, it is probable that the "*lipome herniaire*" of Monod and Delagenière may be largely responsible for the rupture. With regard to the rare form of intra-peritoneal cystocele two explanations have been offered. Gerard-Marchant writing in 1876 suggests that in an ordinary case of inguinal hernia the intestine or omentum normally present may, on an occasion of reduction, become in consequence of some trifling inflammatory condition adherent to the peritoneally clad posterior and superior part of the bladder. This adhesion may become firm and in the subsequent descent of the omentum or gut implicated the attached bladder may also be dragged down. Leroux quotes a case observed by him, where he attributed the vesical involvement to epiploic adhesions such as this. This theory, simple and fascinating though it is, is in certain cases inadmissible, for no adhesions are discovered. Such a case is recorded by Krönlein. In these later cases an unusually copious distension of the bladder has been noticed, and it is suggested by certain French authors (Duret, Jaboulay, Villard, and others) that in such cases the peritoneal traction causes the ballooned posterior part of the bladder to topple over to the affected side "*par bascule*" and to become in that way engaged in the hernial orifice. As so few cases have been recorded, it seems impossible at present to attempt any completely satisfactory explanation, but it is probable that one or other of the causes mentioned will account for the majority of the cases.

To sum up the causes leading to the development of a hernia of the bladder we may state the matter thus:—1. There must be a condition of *permanent vesical distension*. As a result of this enlargement the normal anatomical relations of the bladder undergo considerable modification. The increase is not merely in the vertical direction, but also in the transverse. The bladder is therefore brought into relationship with the inguinal fossæ. 2. There must be a condition of *motor insufficiency* of the bladder. The wall is thinned in certainly the great majority of cases. Szalistschew gives it as his experience that the bladder wall may be not only not thinned but actually thickened and the muscular fibres considerably hypertrophied. A glance through the recorded cases, however, is amply sufficient to show that the atrophy of the muscular coat is incomparably more frequent. 3. There must be a condition of *laxity of the abdominal wall*, especially in the lower half, or of undue patency of the inguinal canal and unusual size of the abdominal rings. A bulging of the lower abdominal wall is very common in cases of hernia occurring in middle or old age. It has been described and figured by Glenard, Macready, and others.

4. As supplementary to these three there is also necessary the *increase of intra-abdominal pressure, the "effort"* upon which Nélaton in 1857 was the first to lay definite emphasis.

Undoubtedly these essential conditions find themselves represented to perfection in the case of prostatic enlargement. In an enlargement of the middle lobe of the prostate, of such kind that the lobe acts as a ball-valve, they would be more clearly defined than in other forms of prostatic enlargement. In those cases where prostatic hypertrophy is not a factor, and to some, at present uncertain, extent even in these, we must allow some share as a causative factor to the "*lipome herniaire*" of Monod. The occurrence of this massive deposit of fat is much too frequent to be merely a coincidence. It is only right, however, to state that its influence is strenuously denied by many observers, among whom Lejars and Imbert are the most emphatic.

It will be seen from this description that cystocele is both primary and secondary. *Primary cystocele* results from two conditions: (1) in which the bladder through persistent over-distension, associated with muscular atony, laxity of the abdominal wall, and "effort," is forced into the inguinal canal; and (2) in which the traction or fixation of a lipoma causes the descent of the organ. *Secondary cystocele* results from (1) the traction of a pre-existing hernia; and (2) the protrusion of the peritoneally clad portion of a lax, distended bladder into a hernial sac of old standing. This may be spontaneous or the result of omental adhesion. The omentum in a hernia may, as a result of injury, temporary strangulation, or other cause, suffer inflammation. On reduction it may be in contact with, and adhere to, the bladder, and thus be responsible for the hernial descent of that organ.

SYMPTOMS AND SIGNS.

At the outset it must be admitted that any special signs and symptoms of the implication of the bladder in a hernia may be entirely absent. The number of cases that have been diagnosed before operation does not amount, at a generous estimate, to more than 5 per cent. of the whole. A reference to the table which follows shows that in a remarkably large number of the recorded cases the first appreciation of the implication of the bladder came after its wounding during the operation. In some few cases a diagnosis before operation has been made, and in these, of which my own first case is a striking example, the symptoms do not admit of misconstruction. The signs of a bladder hernia of moderate or large size are those of a hernia which at times contains fluid. The tumour is generally rounded, smooth, soft, and fluctuating. The fluid is capable of reduction under pressure, and in a few cases it has been recorded that the patient has become expert in assuming a certain posture in order to facilitate the return of the urine. The size of the hernia is liable to rapid and considerable alteration. Within a couple of hours it may alter from the bulk of a lemon to the size of an average water-melon. On percussion such a tumour is almost wholly dull. The tumour in whole or in part, except in the rare intra-peritoneal form, is irreducible. The portion left behind after reduction has been carried out as far as is possible, is thick and doughy in consistence, being made up of the "*lipome herniaire*." As Sir Astley Cooper pointed out, the scrotal swelling is distinguished from hydrocele by the fact that it is not translucent.

The functional characteristics are striking. The chief of these is the "*miction en deux temps*," the divided micturition. A patient so affected voids urine and empties the portion of the bladder in the pelvis. Then on pressure being applied to the hernia the urine it contains is returned within the pelvic portion of the bladder and thence passes by the urethra. Micturition is in two stages and is associated with a simultaneous lessening of the hernial swelling. If the bladder, after being naturally emptied, is filled by the injection of lotion the fluid will pass through the canal and distend the hernial tumour. In some cases it has been possible to pass a sound or a catheter through the urethra into the bladder and out by the inguinal canal, so that the beak could be felt in the hernia. Pressure upon the hernial swelling produces a desire, which with increasing pressure becomes irresistible, to micturate and a few drops of urine may be involuntarily passed. In a few of the cases it has been remarked that there was considerable difficulty in emptying the scrotal portion of the bladder into the pelvic portion on account of the narrowness or compression of the joining isthmus. Guterbock emphasises the importance of a rectal examination, asserting that the normal bulging of a distended bladder towards the rectum is absent.

Hernia of the bladder is very rarely strangulated, but not infrequently there have been symptoms simulating and suggesting strangulation. Such are nausea and vomiting, abdominal distension, obstruction of fæces, and flatus. They, however, have never had the acuteness of those present in true strangulation. The most distressing symptom in a case under my care was hiccough, which was persistent and exhausting. In two cases recorded by Hermes where symptoms suggesting strangulation were present no gut was found in the sac on operation. In the severer cases the general aspect of the case would suggest omental rather than intestinal strangulation. The following table based upon one prepared by Brunner, and including, so far as I am aware, all the recorded cases, shows almost at a glance the chief features of the cases.

HERNIA OF THE BLADDER

Total recorded cases, 171.

Cystocele diagnosed; no operation				13 cases.
(In three of these diagnosis was confirmed after death.)				
Cystocele diagnosed; operation				6 cases.
Bladder wounded (resection)	1	6		
Bladder not wounded	5			
Cystocele found; after wrong diagnosis				4 cases.
(3 diagnosed as abscess, 1 as sarcocele)				
Cystocele, first discovered at operation				107 cases.
Bladder recognised and not wounded			49	
wounded and recognised			58	
As follows:—				
Wounded accidentally, though recognised			2	58*
Unexpectedly wounded			26	
Intentionally incised			23	
Being mistaken for:—				
The sac	3	23		
A second sac	8			
Tumour	4			
Cyst	1			
Omentum	2			
Lipoma	2			
Not mentioned	3			
Incised for diagnostic purposes			5	
" to confirm diagnosis			2	
Cystocele, first recognised after operation because of wounding of bladder				22 cases
Wound not noticed at operation	6	22		
Supposed to be sac	9			
" " second sac	5			
" " lipoma	2			
Cystocele, found post-mortem				19 cases

* Bladder wounded and recognised .. 58

The cases were dealt with as follows:—

	No. of cases.	Result: Healing without fistula.	Result: Fistula.	Result: Death.
Bladder simply left open	2	0	2	0
" stitched to skin	4	0	3	1
" drained by tube	1	0	0	1
" ligatured	3	0	1	2
Fastened in ordinary suprapubic incision made for the purpose	1	0	0	1
Suture of bladder—simple	10	5	2	3
" double layer	15	13	2	0
" triple layer	12	6	5	1
Suture; no details	10	4	5	1
Total	58	28	20	10

DIFFERENTIAL DIAGNOSIS.

Brunner makes the apt remark that there is "scarcely any province in surgery where so many mistaken diagnoses are made" as in hernia of the bladder. A reference to the preceding table shows that out of 171 cases which are given in some detail only nineteen cases were diagnosed and in only nine of these are we certain that cystocele existed; six were proved by operation and three by post-mortem examination. In my own three cases a diagnosis was made in one, in the second the herniated portion of the bladde had a capacity only equal to that of a walnut and therefo caused no symptoms, and the third was an "operati cystocele." My own first case had before I saw t patient been treated as hydrocele and tapped on t occasions. The false diagnosis of hydrocele, indeed, is t most commonly indulged in, and in cases where a la portion of the bladder is implicated, and where the wa thin and the communicating neck is no wider than " largest wheat straw," one can readily understand tha physical conditions in the two cases are apt to be conf A cystocele of any bulk can, however, be distingu by the following differences: it is opaque, is flu reducible, reduction is attended with the desire to u and micturition is effected in two stages. The pr of fat in a hernial [illegible] with a [illegible] lateral bladder. On the reduction of the [illegible] which is [illegible] there is not usually that [illegible] the thickening of the inner and posterior part of the sac to be felt [illegible] diagnosis [illegible]. A case illustrating the difficulty of diagnosis is related by [illegible]. At the [illegible] of an operation for a strangulated hernia [illegible] to notice that [illegible] the external [illegible] the bladder had [illegible] subsequent [illegible]. From a clinical point of view we should describe two classes of cystocele, the "manifest" and the "latent." The "manifest" would include [illegible] owing to the large portion of the bladder involved the signs and symptoms are unmistakable, and the "latent" those where only a trace of the viscus is involved and [illegible] signs or symptoms are all [illegible] entirely wanting.

TREATMENT

It is, of course, quite impossible for a patient suffering from a hernia of the bladder [illegible] the intraperitoneal [illegible] operation is [illegible] to wear a truss. So much [illegible] the inconvenience and the danger of the case. In [illegible] there is decided objection upon [illegible] operation should be performed. The frequency with which the bladder has been wounded during operation makes it a matter of considerable importance that the surgeon should be able to recognise the bladder when it exists as a hernial content. There are two chief considerations which facilitate this recognition: (1) a thickening or a deposit of fat at the inner and back part of the sac, and (2) the presence of interlacing muscular bundles in a similar position. Any thickening of the upper part of the sac, especially on the inner side, should be treated with the profoundest respect. An examination of the recorded errors shows that in many cases even where the thickening has been noticed sufficient care has not been exercised in investigating its nature and harm has followed. Unless the neck of the stripped sac is perfectly free and is normal in appearance and to the touch it should not be transfixed, ligatured, or twisted. I am aware that in many cases the bladder has been wounded because it was not seen. The importance, therefore, of a clean stripping of the sac and of a minute examination of its neck can hardly be over-emphasised. The advantage which operations like Bassini's, Halsted's, and Lockwood's exhibit in this regard need not be enlarged upon. If a fairly large area of the sac is involved as a covering of the bladder it must not be stripped up. The peritoneum must be entered [illegible] bladder and on the other side *close up to the ring*, and the circular wound stitched up by continuous or interrupted *sutures*. The bladder loosened gently from its surroundings (it has been torn even when recognised and therefore requires delicate handling) is returned into the abdomen, and the rings and canal are stitched up in such manner as is considered most satisfactory. In the great majority of, if not in all, cases it will be necessary for the patient after operation to wear a truss. The operation may be said to have for its object the rendering of the condition of the inguinal region such that a *truss can be readily and safely worn*.

When the bladder is wounded and recognised the best plan undoubtedly is to stitch up the wound with stitches which do not include the mucous membrane. A single layer, or even double or triple layers of sutures have been employed. Probably two layers are ample. In some cases the bladder has been wounded and not recognised until some time after the operation. Within 12, 24, or 48 hours it may be noticed in such a case that the dressings are soiled with a more or less copious discharge of thin yellow fluid, or blood may be present in the urine voided after recovery from the anæsthetic. In such cases the wound must be re-opened, and if possible the bladder wound should be accurately stitched up. A urinary *fistula* may result and may persist for an indefinite period or it may *gradually* close up and the wound heal soundly. Monod and Delagenière suggest that when the bladder is wounded that portion of it which is *implicated in the hernia* should be resected and the wound left in the bladder stitched up. Lanz advises the turning up of the peritoneal flap before resection, so that the line of sutures in the bladder may be covered in by the flap when replaced. I can conceive no possible advantage from resection unless gangrene of the wall of the bladder were present, and as this is an exceedingly unlikely complication the method is not one to be advocated. If it is ever justifiable this procedure of Lanz would certainly add a measure of safety.

PROGNOSIS

The really serious part of hernia of the bladder results from the attendant [illegible]. There is nothing in the bladder involvement as such that is untoward. The bodily feebleness, the prostatic enlargement with its secondary effects on the bladder, kidneys, or general health, and the not infrequent *wounding of the viscus during operation are the circumstances* that tend to add to the seriousness of the case. When the presence of the bladder in a hernial sac is merely an incident without any bearing upon the case the dangers are those merely of an ordinary hernia.

CRURAL CYSTOCELE

What has been written of inguinal cystocele applies almost equally to the femoral variety. 33 cases are recorded by [illegible] in a recent pamphlet; of these 20 occurred in women. The part played by the prostate in the production of hernia of the bladder in men is assumed very [illegible] its attendant conditions in women. According to the records of these cases, which in some respects are not sufficiently detailed, 20 cases are extraperitoneal, eight are paraperitoneal and one is intraperitoneal; of the rest it is impossible to speak with accuracy. Only three patients presented symptoms sufficiently definite to render a diagnosis possible. These cases are recorded by [illegible] and Guinard. During operation the bladder was wounded seven times, being mistaken for the *sac* or [illegible] (Hahn) for a second sac.

TUBERCULOUS DISEASE OF THE KIDNEY: ITS ETIOLOGY, PATHOLOGY, AND SURGICAL TREATMENT.

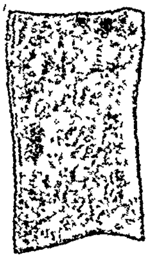
By DAVID NEWMAN, M.D. GLASG.,
SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

(Continued from p. 531.)

ASSOCIATED with tuberculous disease of the kidney there are usually more or less specific inflammatory changes in the mucous membrane of the pelvis, the ureter, and the bladder. The lesions in these parts generally follow the disease of the kidney. The affection of the conducting and collecting portions of the urinary tract is brought about in the following way. If the primary focus be situated in the medulla of the kidney the disease spreads into the renal substance and the tuberculous material breaks down and discharges by bursting into the pelvis and infects the mucous membrane secondarily. Or, if the pelvis is primarily involved the debris flowing into the bladder in its course infects that viscus.

Infection by invasion along the lymphatics of the kidney from foci in the lower urinary tract.—Ascending renal tuberculosis is by no means an uncommon malady. By injecting the ureter of living animals or by studying the course of events of the disease in the human subject we can easily follow the course of events. The experiment performed by Albarran throws considerable light upon this subject. By injecting the ureter with pure cultures of tubercle bacilli and ligaturing it below the point of puncture he was able to study the process by which infection proceeded along the duct and the morbid lesions associated therewith. The infection extends upwards from the bladder to the kidney. The bladder is usually contracted, its muscular coat is hypertrophied, and the mucous membrane is indurated. In the ureters and the bladder the tuberculous process begins by the formation of tubercles in the mucous membrane, and these breaking down form in a typical manner the so-called lenticular ulcers (Fig. 8) which are characterised by a flat base covered by caseous matter and sharp rugged borders within which little miliary nodules are situated. The ulcers are at first circular, usually superficial, their edges are slightly raised and are surrounded by a pale anæmic zone set in a deeply hyperæmic mucous membrane. In the bladder these ulcers frequently coalesce, forming larger ones of variously irregular forms. Their favourite seat is—probably on account of the mode of infection—the trigone and fundus of the viscus. In this form of the disease the kidney may be rapidly destroyed by hydronephrosis and the swelling may attain an enormous size through dilatation of the kidney by its fluid contents, and at the same time the surface of the distended pelvis and the renal parenchyma may become occupied by tuberculous foci. The infection of the kidney through the pelvis has been already described. In ascending renal tuberculosis the course of events is so different from that which is seen in the descending variety of the disease that clinically they can be distinguished easily from one another. The former is characterised by the early obstruction of the escape of urine from the pelvis, hence the most prominent features of the disease are symptoms and signs indicative of hydronephrosis or pyonephrosis. But the contents of the dilated pelvis differ in tuberculous disease from that observed in a purely septic lesion. They may be purulent but not necessarily so; indeed, they may be quite aseptic and may consist of broken-down renal tissue and tuberculous débris, or they may present the appearance of very soft, putty-like material. The renal sac in such instances is usually unilocular but it is divided more or less by deep septa which represent all that remains of the calices. These pouches generally correspond with the prominences, while the septa mark the depressions, on the surface of the kidney, and sometimes the latter are so deep that they give the kidney a distinctly lobulated appearance on its external surface. In some instances the obstruction to the ureter is complete only occasionally, and then the retention causes renal colic, while in the intervals the contents of the kidney escape and appear in the urine. The urine in such cases is usually clear for some days, during which time the subjective symptoms are aggravated; then suddenly the urine becomes turbulent, a sudden escape of tuberculous débris takes place, and for a time the patient is relieved.

FIG. 8.



Tuberculous ulceration of the ureter.

Extension by contagion along the lumina of the excretory ducts.—This method of extension is seen in cases of ascending tuberculous lesions and the progress is much the same as that which is observed in the conveyance of septic infection. In some cases the whole route of infection may be traced in the walls or on the surface of the bladder, the ureters, and the pelvis, right into the uriniferous tubules of the pyramids. These tubules are found in many instances to be blocked by colonies of tubercle bacilli alone, but more frequently they are mixed with other organisms The aggregations of microbes are surrounded by areas of inflamed tissue the exact character of which depends upon the age of the lesion. The foci are limited to the medullary portion of the kidney at first. In the early stage the specific inflammatory changes are slight and consist chiefly of degenerative processes in the epithelium and infiltration of leucocytes around and between the tubules, but gradually as the disease extends from the original centre disintegration of the renal parenchyma occurs and small cavities or abscesses form. The organisms may by plugging the lumina keep back the excretion and dilate the tubules. In this way the vitality of the epithelium and of the basement membrane becomes impaired and ultimately rupture occurs and the contents of the tubule is permitted to escape into the lymphatic spaces. Then the organisms rapidly spread and very soon excite fresh lesions in more distant parts of the organ.

Infection by the extension of the disease from other organs by continuity.—The isolated position of the kidneys protects them from infection by this process. Their deep situation in the lumbar region, far away from external influences, except through the lower urinary tract and the blood-stream, shut off from the abdominal cavity and surrounded by a firm fibrous capsule, make contagion by continuity difficult. But as we find in septic lesion of the kidney so also in tuberculous lesion, it must be recognised that contagion by this means does occur. The extension of tuberculous infection through the capsule is the least common channel of invasion of the renal substance, so that even in cases where the suprarenal bodies are involved in the tuberculous process the corresponding kidney is rarely affected. I have met with only one such case; in that case the kidney became infected by continuity from a tuberculous empyema. The patient was under the care of Dr. Wood Smith while he was physician in the Glasgow Royal Infirmary. The case was one of chronic phthisis pulmonalis, in which perforation from a cavity in the lung into the pleura occurred at the left base; this led to an empyema between the diaphragm and the base of the left lung extending upwards to as high as the seventh rib. The empyema was known to exist for one month. Ultimately it perforated through the diaphragm and surrounded the left kidney. At the post-mortem examination there were found in the substance of the kidney numerous small tuberculous foci but there was no evidence of extension of the disease to the pelvis, the ureter, or the bladder. The infection evidently spread from the subcapsular lymphatic space to the lymphatics surrounding the capillaries and the uriniferous tubules.

The comparative frequency of tuberculous disease of the kidney may be judged by the following statistics quoted by Roberts: "Embracing both primary and secondary deposits, the latter being, especially in children, by far the most frequent, out of 1317 tuberculous subjects examined in the Pathological Institute of Prague (out of a total of 6000 bodies) tubercle in the kidney was found 74 times, or in the proportion of 5·6 per cent., of tuberculous subjects[1] Among 315 tuberculous children Rilliet and Barthez found tubercle in the kidneys 49 times, or in the proportion of 15·7 per cent." Dickinson also alludes to the relative frequency of renal tuberculosis in children and in adults, and in a table compiled from the post-mortem records of St. George's Hospital and the Hospital for Sick Children, Great Ormond-street, he shows the frequency of tuberculous formations in the kidney and other organs in 600 post-mortem examinations, the subjects of 300 being under the age of 12 years and those of the other 300 of the age of 12 years and upwards. Of the former group 49, and of the latter group 17, suffered from tubercle in the kidney. These results correspond so closely with those of Rilliet and Barthez that there can be little doubt that renal tuberculosis in one form or another is specially a disease of early life, but whether the renal lesion is a primary or a secondary one is not shown in the statistics just referred to. Dickinson does not distinguish between the two forms, miliary and caseous; for "the miliary," he says, "become caseous as they enlarge, so that although in some cases there may be only one or only the other, yet they are continually intermixed and inseparable, as different results of the same process" From the surgeon's standpoint it must appear, however, very important to distinguish between a disease which involves the whole system and another which primarily attacks an individual organ or part of an organ, even although they are histologically the same pathological process. With the distinction just referred to in view Morris shows, by an examination of the records of the Middlesex Hospital, that of the 40 cases of tuberculous kidney met with in 2610 necropsies, 29 were miliary (secondary) and 15 were strumous (primary). Of the 29 cases of miliary tuberculosis 18 were males and 11 were females, and in 28 out of the 29 cases both kidneys were diseased, while in the 15 cases of primary renal tuberculosis (nine males and six females) both kidneys were diseased in eight patients Another point worthy of note is the different periods of life at which the two forms of disease occur. In the miliary (secondary) tuberculosis 12 cases occurred in persons under 10 years of age, eight in persons between the ages of 10 and 30 years, six in persons over 30 years of age, and three in persons whose ages are not stated. In the scrofulous (primary) tuberculosis no cases occurred in persons under 11 years of age, five occurred in persons between the ages of 11 and 30 years, seven in persons over 30 years of age, and three in persons whose ages are not stated.

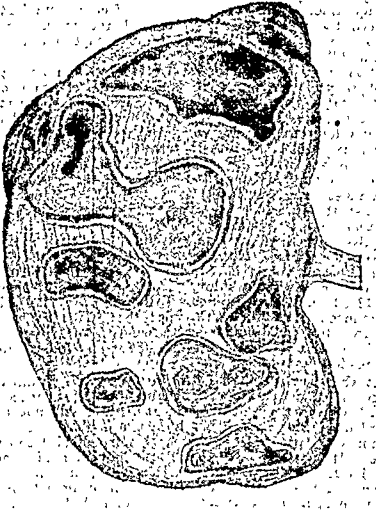
Symptomatology.—In all cases of pyuria with the renal symptoms in men a careful examination should be made of the genital organs and of the prostate for tuberculous disease, as very often a clue which is of value in diagnosis may be thus obtained. If the symptoms are associated with rapid emaciation, anæmia, elevated evening temperature, and rapidly progressing marasmus tuberculous disease should be suspected. When the disease is limited to the parenchyma of the kidney the symptoms may be insignificant and ill-defined. When the bladder, ureter, and pelvis are not involved—that is to say, when the infection is purely tuberculous and localised to the kidney—there is seldom much pyrexia. The urine is acid and the quantity of pus is small. There is not generally much pain in the affected organ nor is the kidney much enlarged. The severity of the symptoms varies according to the form of the tuberculosis. In many cases it is a noteworthy fact that marked and advanced disease of the kidney, and even of the pelvis and ureter, may exist for long periods with total absence of symptoms pointing to a lesion in the urinary tract; hence the disease may destroy one kidney and block its ureter without being recognised. The only indications of departure from health may be impairment of the general nutrition, indicated by anæmia and emaciation, so that only late in the history of the case the attention of the physician may be directed to tuberculous disease. But when the mucous membrane of the pelvis or calices becomes involved, or when abscesses of the kidney burst into them, renal pain becomes marked. It is difficult to make any general statement as to the constitutional symptoms of tuberculosis of the urinary tract: their characteristics depend not only upon the extent of the disease and the locality involved but also upon the health or disease of other organs. In many cases emaciation and anæmia are marked, especially when there is mixed infection and the temperature is high or variable. Instances are met with, however, where tuberculous disease has existed in one kidney for a long period without any perceptible loss in weight or increase in temperature. In instances where the tuberculous lesion is small in size and localised a careful record of the temperature may reveal a slight afternoon rise of half a degree or of a degree. This slight variation in temperature in renal tuberculosis distinguishes it from a septic kidney. In the latter the variations are much greater. The fever arises in each from the action of the microbes and the amount or virulence of toxin produced by them, and consequently the pyrexia is to some extent a gauge of the activity of the morbid process. In the great majority of cases the thermometer is of much assistance, but it must be borne in mind that the pyrexia may depend more upon septic lesions in other parts than upon the aseptic renal malady. The temperature of the patient is generally from two to three or even four degrees higher in the evening than in the morning, or there may be intermittent periods of fever lasting for several consecutive days. Pain in renal tuberculosis depends upon whether the pelvis and ureter are involved in the disease. When the kidney parenchyma alone is implicated severe pain is seldom complained of and the patient only experiences a dull, dragging sensation in the loin. In cases of ascending tuberculous disease, or in advanced cases of primary renal tuberculosis where the pelvis, ureter, and bladder have become implicated, pain is often a distressing symptom. The pain sometimes simulates that of stone in the bladder. Occasionally, however, it is limited to the lumbar region or it may extend down the thighs. Frequent micturition is invariably accompanied by pain, which commences to be severe about *the middle of the flow, increases towards* the termination, and then subsides almost immediately the bladder is emptied. There is seldom an escape of blood with the last drops of urine and the pain and frequency are as marked during the night as in the day. In these respects the strangury of tuberculous disease differs from that met with in vesical calculus. Vesical irritation, shown by *incessant and painful micturition,* is a frequent and almost characteristic symptom of tuberculous disease, and this symptom may be present to a marked degree without the bladder being diseased. It is often the first symptom which attracts the patient's attention and makes him seek advice. Strangury is met with in all varieties of the disease, from the earliest to the latest stages, but it is generally most marked in the ascending lesions. It may, however, disappear or become much abated for considerable periods. In many cases swelling in the renal region is not pronounced. Sometimes, however, the kidney attains considerable dimensions and occupies the greater part of one side of the abdomen. Renal swelling sufficiently large to be made out by palpation may be produced by extensive disease of the cortex alone. (Fig. 9 shows a very good example of enormously enlarged tuberculous kidney, where the increase in bulk was due to infiltration of the parenchyma of the kidney rather than to any great distension of the pelvis or calices. The kidney weighed 28 ounces and contained a large number of irregular-walled cavities lined by greyish-white pultaceous material.) When this is so the swelling is found to be uniform in size when examined from time to time. On the other hand, when the renal swelling is due to obstruction of the urinary tract, giving rise to hydronephrosis or pyonephrosis from time to time, great variation in the size of the kidney may be observed. In about one-fifth of the cases recorded, and in the majority of those operated upon for strumous disease, the tuberculous pyonephrosis was discovered by palpation during life. Increase in the bulk of the kidney, while it must be regarded as an important sign of disease, is one which when present in connexion with the tuberculous lesion usually indicates that the disease has so far advanced as to cause diminution of the lumen of the ureter or other obstruction to the flow of urine. It is important also to ascertain whether or not the swelling is limited to one side; this may be done by palpation and percussion in some cases, while in others the only reliable mode of testing the extent of the disease is by catheterising the ureters. In tuberculous disease the renal swelling may form the centre from which the pain starts and from it the pain may extend down the line of the ureter to the bladder and testicle, across the abdomen to the opposite kidney, to the spine, down the groin, or along the outside of the thigh.

FIG. 9.



Enlarged kidney (weighing 28 ounces) due to tuberculous nephritis and the formation of cavities in the renal substance. (Royal Infirmary Museum, Series VII., M 10.)

It is to the diagnosis of tuberculosis in the early stage that we must especially direct attention, seeing that in its later development the aid of the surgeon is of little avail. The urine furnishes important information, and in all cases of s pected tuberculous disease careful analysis and microsco examination of it should be made previously to th ployment of any instrumental examination. One first indications of a tuberculous lesion in the kidney is polyuria, due, probably, to hyperæmia of the organs produced by the presence of tubercle bacilli or their toxins. It is a symptom which is very apt to be overlooked, unless when associated with albuminuria. The presence or absence of albumin seems to depend upon whether or not the tuberculous lesion freely communicates with the urinary tract. If the disease is located in the kidney substance all inflammatory products are kept shut off and do not mix with the excretion. At the same time the portion of the kidney not implicated in the disease continues to excrete healthy urine. If, however, there is a free communication between the active diseased area and the urinary tract, serum, blood-corpuscles, and leucocytes escape and give the urine an albuminous reaction.

Hæmaturia is seldom profuse, but it may occur as a premonitory symptom long antecedent to the development of a gross renal lesion. It is by no means uncommon to meet with cases of profuse and frequent hæmoptyses long prior to the development of any recognisable physical signs of pulmonary phthisis; so also in renal tuberculosis hæmaturia may be present as a premonitory symptom of the disease. Those who have had much experience in the post-mortem room must have seen cases of chronic phthisis pulmonalis where shortly before death hæmorrhages have occurred and blood has escaped into the parenchyma of one kidney or into the pelvis and where on minute examination the renal tissue or even the effused blood was found to be occupied by tubercle bacilli, yet on microscopical examination the histological structure of the kidney was little altered and beyond the blood infiltration presented the same microscopical appearance as its fellow on the opposite side. In such cases numerous tubercle bacilli may be found in the thrombosed vessels of the Malpighian tufts without any inflammatory changes having taken place.

But while hæmoptysis has been looked upon as a valuable danger-signal of phthisis pulmonalis, even when unaccompanied by other physical signs, hæmaturia has not been regarded in the same light, although doubtless in some instances it carried with it the same warning of trouble to come. Hæmaturia is often the first indication of danger that induces the patient to seek advice, and in many instances unless repeated and most minute examinations are made the medical adviser may find it difficult to arrive at a satisfactory explanation of the symptoms. In tuberculous disease the urine presents very marked variations in the different stages of the malady; in the initial phases of the affection the presence of the virus induces a congested condition of the organ, and hæmorrhages occur which are analogous to the early hæmoptysis of pulmonary tuberculosis and are probably due to a local interference with the circulation arising directly from the intimate relationship of the tuberculous deposit with the vascular supply.

CASE 6. *Profuse hæmaturia with slight pain in the left kidney recurring thrice; no other deposit in the urine and no swelling in the lumbar region; apparent recovery for two years followed by a relapse of the symptoms and a swelling in the left lumbar region; muco-purulent deposit in the urine and tubercle bacilli; no vesical irritation.*—A young woman, aged 18 years, consulted me in September, 1893, on account of a profuse hæmaturia which had occurred a fortnight previously. No reason could be assigned for the onset of the bleeding, and it was unaccompanied by any pain over and above a sense of fulness and weight in the left renal region. A careful examination of the urine failed to reveal any abnormal constituents beyond a small trace of blood, but the hæmaturia had practically disappeared at the time I saw the patient. Three months after this first hæmorrhage a second attack, not so profuse or so prolonged as the first, occurred and two months thereafter a third attack, all without any concomitant symptoms. On account of the difficulty in forming a diagnosis an examination of the bladder was made during the last attack and blood was seen issuing from the left ureter in a distinct cloud. It was therefore evident that the hæmorrhage was of renal origin, but as there were no symptoms pointing to the nature of the malady complete rest in bed was enjoined and the patient made what was regarded at the time as a complete recovery. Two years after the first hæmorrhage a fourth hæmorrhage occurred; this was associated with considerable pain in the left lumbar region and a distinct swelling could be made out by palpation. Examination of the urine two weeks after the hæmorrhage occurred showed it to contain a deposit of muco-purulent material as well as blood corpuscles, and on microscopical examination tubercle bacilli were discovered. Still, there were no symptoms present indicating any irritation of the bladder. The temperature was now elevated for the first time and the patient suffered from night-sweats, but there was no emaciation, loss of appetite, or serious constitutional disturbance.

CASE 7. *Hæmaturia 13 years previously to admission, and again nine years after the first bleeding; large tuberculous pyonephrosis.*—A man, aged 39 years, was admitted to the Glasgow Royal Infirmary on April 28th, 1896, complaining of pain in the region of the right kidney. The patient's first trouble in connexion with the urine dated back 13 years, when he had a slight attack of hæmaturia accompanied by pain over the right kidney, but these symptoms passed off in a few days. The patient had been in the infirmary in February, 1892, suffering from hæmaturia. He first noticed blood regularly present in his urine in November, 1895. He, however, was able to continue at work until the end of January, 1896, when he came into the hospital. At that time the hæmaturia was very considerable. He said that it was only three weeks previously to admission that he noticed anything like severe pain in the right side, and since the pain came on he had not noticed any blood in the urine. On examination a very distinct fulness was found in the right lumbar region. The whole space between the liver and the crest of the ilium was dull on percussion, and on pressure considerable tenderness was produced. The thoracic organs and the other abdominal organs were normal, so also was the bladder. The urine contained a considerable quantity of pus and some blood, and tubercle bacilli were present. The left kidney was healthy. On operation a large tuberculous kidney was discovered on the right side; it was scraped and evacuated.

In early hæmaturia the urine contains blood, but is free from tuberculous deposits such as can be recognised by the naked eye or even by the microscope. Cultivation observations and inoculation experiments may, however, detect the presence of tubercle bacilli.

Late hæmaturia from destructive tuberculous processes in the pelvis and renal parenchyma.—When the kidney parenchyma and the calices become more seriously involved the characteristics of the urine are more distinct, but this is not always the case. The physical characters of the urine are in some instances such that one can with certainty state that the urinary tract is the seat of a tuberculous lesion, while in other cases the excretion may be to no appreciable extent altered from the normal. Before destructive processes commence within the renal pelvis or substance traces of albumin and small quantities of blood may be detected, but when the tuberculous deposit has commenced to break down and to evacuate into the ureter the quantity of albumin is increased, the urine is liable after a time to become alkaline, and along with greater or less quantities of débris of renal tissue pus appears in considerable quantity. The albuminuria differs from that of Bright's disease in that the urine is not clear, but contains much mucus; it is viscid, cloudy, and opaque, and it does not contain tube-casts. The deposit contains small caseous masses mixed with renal débris, and on standing, although a considerable amount of pus may be precipitated, a certain quantity remains suspended and imparts a cloudy appearance to the fluid.

It is only in rare instances that profuse hæmaturia occurs in renal tuberculosis. Trautenroth[1] records a case of a woman, aged 24 years, who was the subject of pulmonary tuberculosis in its early stage but who also suffered from profuse hæmorrhage from a tuberculous kidney which necessitated nephrectomy. The pelvis of the kidney was filled with coagulated blood and upon one of the papillæ a considerable ulcer was discovered. The parenchyma of the kidney was the seat of a diffuse tuberculosis. The urine before the operation was found to contain tubercle bacilli. The patient made a good recovery. Routier[2] records a somewhat similar case where the right kidney was the seat of a large tuberculous ulceration. Severe hæmorrhage occurred and continued during 17 days associated with renal colic. On making pressure over the right kidney blood was seen to escape from the right ureter by the cystoscope. The kidney was removed and the patient made a good recovery.

CASE 8. *Occasional slight hæmaturia followed by one profuse bleeding in advanced renal phthisis.*—The only case worthy of note where severe hæmaturia occurred in advanced tuberculous disease was that of a man, aged 37 years, who was admitted to the Glasgow Royal Infirmary on June 16th, 1895. The patient was under treatment for a long period for tuberculous disease of the right kidney, and whilst occasional slight hæmaturia was observed from time to time it was not until March, 1897, that a large amount of blood escaped and at that time a very considerable hæmorrhage, amounting as the patient thought "to about a pint of blood and blood clot," escaped, but as far as is known no recurrence of bleeding of such dimensions occurred. Although tuberculous bacilli are classified as non-pyogenic, and properly so, in many cases of tuberculous disease before mixed infection has occurred large numbers of leucocytes not distinguishable by the microscope from pus may be found. In pure tuberculous disease the urine is acid and sterile from pyogenic microbes. For diagnostic purposes it is therefore necessary to draw off through a sterilised catheter a quantity of urine and to make cultures. The presence of pyogenic micro-organisms does not exclude the possibility of the disease being tuberculous, but their absence greatly strengthens the presumption.

---

[1] Centralblatt fur Chirurgie, 1896, No. 16.

[2] Bulletin et Mémoires de la Société de Chirurgie de Paris, vol. xxi., p. 148.

As the disease advances the odour of the urine as a rule becomes more and more offensive; the fluid deposits large quantities of mucus and triple phosphates and on examination it is found to be highly albuminous. Occasionally while the urine is pale and of low specific gravity there may be evidence of retention on the diseased side, as shown by, increase in the renal swelling, with perhaps indistinct fluctuation and pain, accompanied by general constitutional disturbance, or there may be complete suppression, death being ushered in by uræmic symptoms.

In addition to the diagnostic points already indicated the detection of the tubercle bacillus in the urinary débris is of great value. It is when tuberculous lesions begin to break down that tubercle bacilli are most abundant, and sometimes their number is very large. Several examinations are required before it can be concluded from negative results that the case is not tuberculous. It is more difficult to obtain the bacilli from urine than from sputum; they are less numerous in proportion to the medium in which they lie. decomposition destroys them more rapidly, and smegma bacilli are apt to be mistaken for them. The method is as follows Allow a quantity of urine to stand in a conical glass in a cold place for not more than six hours and from the deposit select a small quantity of débris and place it in a glass of ¾ per cent. salt solution. It is more rapid and more reliable, however, to obtain separation of bacilli by the employment of the centrifuge. This method should always be resorted to when the numbers are small or when the urine contains much mucus or blood. When large quantities of mucus are present it may be necessary to render the urine slightly alkaline before using the centrifuge Having placed a small fragment of the débris on a clean cover-glass it should be spread out into a thin layer by pressing another cover-glass against it between the finger and thumb. On separating the cover-glasses a thin film of débris will be found adhering to each The glasses must be air-dried, and then the films may be more firmly fixed by drying over a spirit-lamp or in front of a fire. The cover-glasses are then placed in or, still better, floated upon (with the film side downwards) a solution of aniline magenta or a staining fluid of gentian violet. When the film has become sufficiently stained the colour may be abstracted from all structures other than the tubercle bacilli by passing the cover-glass through a 25 per cent. solution of nitric acid. The action of the acid may be arrested by carefully washing the specimen in pure water. When examining the urinary débris for tubercle bacilli it is necessary in most cases to prepare at least half a dozen specimens. Should bacilli be present they will be recognised by a magnifying power of 750 diameters as minute rod-shaped bodies, coloured according to the nature of the staining fluid employed. They are from three to seven micro-millimetres long; they may be straight, but are more frequently curved or bent upon themselves at an obtuse angle; they are frequently beaded and they occur in bundles or singly From the urine the micro organisms are not easily cultivated, as putrefactive bacteria contaminate the culture and destroy the specific bacilli. Koch, however, states that he has succeeded in cultivating tubercle bacilli from cases of tuberculous pyelitis. In some instances the bacilli in the urine are so few in number that it is difficult or almost impossible to discover them simply by the microscope; in such instances inoculation experiments may help to clear up the diagnosis. Tuberculosis can be communicated artificially to animals in many different ways—in fact, through any of the channels of access to the body: by inhalation, by feeding animals on tuberculous products, or by injection into the serous cavities beneath the skin, or into the anterior chamber of the eye, or into veins. When tuberculous urine is injected subcutaneously into guinea-pigs or into rabbits it produces a typical tuberculosis within 10 or 12 days. The local swelling may break down, caseate, and ulcerate, while the lymphatic glands related to the part become enlarged and firm, and after a time may also caseate and the disease passes on to another group. When injected into the peritoneal cavity tuberculous urine produces an extensive tuberculous infiltration of the omentum and acute tuberculous peritonitis. Normal urine when aseptic becomes absorbed without producing any evil effect or when septic it may produce a suppurative peritonitis. If, however, the experiment is performed with care healthy urine produces a negative result, but if the urine contains tubercle bacilli or their spores acute miliary tuberculosis is developed in the course of a few weeks when the injection is made into the peritoneum, or if the urine is placed underneath the skin a hard tuberculous nodule is formed.

Besides the detection of the tubercle bacillus it is necessary to determine whether the disease is on one or on both sides. I have several times had occasion to examine by ureteral catheterisation cases of tuberculous pyelitis in which it was considered of importance to determine the extent to which the disease had involved one or both kidneys. Catheterisation can only determine the organ to which the tuberculous disease is limited; it cannot indicate the extent of the tuberculous lesion in the affected organ, but to make sure that one kidney is free from disease is a point of importance. The first time I succeeded in doing this was in 1886, when a case was examined and it was clearly shown that the tuberculous lesion was limited to one kidney.

Diagnosis.—The diagnosis of tuberculous disease from other renal lesions is generally easy, but in some instances it is extremely difficult. The most important features which distinguish the disease have already been referred to, so that little requires to be added. The diseases with which tuberculous lesions are most likely to be confounded are renal tumours, septic pyelitis, and pyonephrosis, and changes in the kidney consequent upon the presence of a calculus In calculous pyelitis the purulent stage is slowly developed and is usually preceded by occasional attacks of slight hæmaturia. Indeed, in many cases of renal calculus the appearance of blood in the urine is the first circumstance which attracts the attention and alarms the patient. In calculus the urine passes through a stage during which there is an increase in the quantity of mucus, and this stage is succeeded by the appearance of pus, the quantity of which slowly increases. While these changes are taking place, even through a protracted period, it is remarkable how well the general nutrition of the body is maintained. In tuberculous disease, on the other hand, the purulent stage often develops early; the pus is constantly present, but is not generally in large amount. The pyuria is accompanied from the beginning by a degree of emaciation, by a careworn expression, by evening exacerbations of fever, and by rigors, by drenching night-sweats, and an interference with appetite seldom witnessed in calculous pyelitis.

Tuberculous disease is readily distinguished from malignant tumours of the kidney or renal pelvis by the circumstance that in these diseases the urine seldom contains much pus or débris, and if abnormal at all it is from the presence of blood, which when it once appears continues and may be found in large quantities

The extension of the inflammatory process to the ureter, bladder, and lower urinary tract is strong if not unequivocal evidence of its tuberculous nature. In inflammation arising in the course of calculous pyelitis or pyonephrosis the conducting and collecting portions of the urinary system are seldom seriously implicated, whereas in strumous disease not only are those structures involved, but by a process of infection the generative organs may become invaded also—in the male the vesiculæ seminales, the vas deferens, the epididymis, or the testicle, and in the female the vagina and the ovaries. An examination, therefore, of these parts may assist the diagnosis in doubtful cases.

The diagnosis of the various stages of tuberculous disease is also especially important when operative interference contemplated. In miliary renal tuberculosis secondary to lesions in other organs there may be only slight disturbance of function, the secondary urinary troubles being marked by the symptoms of the primary lesions Sometimes, however, incontinence of urine may demand attention and on examination the condition of the urinary organs may be ascertained.

In chronic nephritis and in tuberculous pyelitis the symptoms are generally well marked and differ materially according to the course of events as regulated by the channel along which infection has taken place. As already indicated, in the descending variety the kidney parenchyma is first involved, and the renal trouble, although it may be primary, is generally secondary to some easily recognised tuberculous lesion elsewhere. There is not usually much increase in the size of the organ to begin with, but sooner or later the lower urinary tract becomes involved in a way and with a degree of certainty not seen in other inflammatory diseases When a mixed infection has taken place and tuberculous abscesses have formed and ruptured into the pelvis pyuria becomes constant, except when the flow from the ureter is retarded by an obstruction, which, however, is usually temporary. At times, therefore, the urine may be almost clear, while at others it is loaded with pus and tuberculous débris. In the ascending form of tuberculous disease vesical symptoms appear early in the course of the disease and are often associated with evidence of tuberculous lesions in the prostate, &c. The ureter becomes involved before the kidney, hence symptoms arising from obstruction, such as renal colic, transitory pyonephrosis, or increase in the size of the kidney from the dilatation of its pelvis, are observed early in the course of the disease.

(To be continued.)

ON THE RELATION OF BLOOD TO LYMPHATIC VESSELS.

BY CECIL H. LEAF, M.A., M.B. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE GORDON AND CANCER HOSPITALS;
LATE ASSISTANT DEMONSTRATOR OF ANATOMY AT
THE LONDON HOSPITAL.

IN THE LANCET of June 18th, 1898 (p 1680), in an article entitled "A Method of Injecting the Lymphatic Vessels," I described a communication which I had observed in the inguinal region of the human subject between a lymphatic vessel on the one hand and a vein on the other. Since that time I have made dissections in the thoracic region in three subjects to determine whether this communication was at all constant and in all these instances have I found it to exist. The following illustrations are drawn from dissections made in these subjects which were hardened by formalin. In Fig. 1 the thoracic duct is double. One of the lower left intercostal veins is seen to terminate not only into the vena azygos minor, but to be connected by a small communicating branch with the left half of the double thoracic duct. In Fig. 4 a large lymphatic trunk is found to terminate directly into the vena azygos major and in the same figure an intercostal lymphatic vessel is seen to terminate in the lowest intercostal vein of the right side. These and other directions show that in the thorax the communication between these two sets of vessels is of no uncommon occurrence and I am inclined to regard it as a normal one. It is frequently found that some of the intercostal lymphatics pour their contents into some of the intercostal veins or into one or both of the azygos veins or that some large lymphatic trunks in the neighbourhood of the receptaculum chyli empty into the vena azygos major. Lippi of Florence in 1825 was the first to maintain that communications between the lymphatic vessels on the one hand and the portal, internal jugular, renal, inferior cava, and azygos veins on the other hand actually existed, but these conclusions were not generally accepted. Recent work would tend, however, to confirm Lippi's contentions. Thus MacAlister[1] says: "The chief communications of lymphatics with veins are at the junctions of the jugular and subclavian veins on each side, but a few communications of smaller size occur elsewhere, as into the internal iliac and posterior tibial veins."

Richard Boddaert[2] experimented on the rabbit, and after ligaturing the thoracic duct and then feeding the animal on a sufficient quantity of fat introduced into the stomach for four hours before its death found that in nearly a third of his experiments (five out of 16) there was a communication between the lymph vessels and the azygos veins. He found, moreover, that by applying forceps near the junction of the azygos vein and the right vena cava superior, and exercising pressure on the lumbar lymphatic vessels, with each pressure the azygos vein became distended, while its contents owing to the admixture of lymph then became much paler. Conversely by pressing on the azygos veins the vessels of communication became distended and their contents from being milky became red. Boddaert has also noticed a large lymphatic trunk pass directly into the external iliac vein. It is always taken for granted that the flow of lymph is from the lymphatic vessel into the vein, and in the great majority of cases, of course, this is the case, but whether it is invariably so along some of these communicating vessels I think there is good reason to doubt In Fig. 1, for instance, the blood is obviously passing from the intercostal vein into the vena azygos minor, and from the direction of the communicating vessel probably through this into the left half of the thoracic duct, or, in other words, it would seem, judging by the direction and relative sizes of the vessels, as though the thoracic duct was here receiving a small venous tributary. In the superior mediastinum I have seen small veins coming from the thyroid gland empty themselves directly into the large lymphatic

unks in this region. By some of the smaller veins emptying hemselves into the larger lymphatic trunks it would seem hat the somewhat sluggish movements of the lymph current ould be thereby quickened. Not only are the veins but lso small arteries in the thorax brought more immediately nto relation with lymphatic vessels than hitherto supposed.

In the specimen from which Fig. 3 was drawn the ymphatic vessels were well marked and at one point, X, I raced from one of them a vessel which at first I took to be vein. On tracing it further, however, it was proved to be branch of an intercostal artery. As far as could be seen ith the aid of a strong magnifying glass this vessel passed irectly at the point X into the lymphatic vessel. In the diagram the other terminal branch of the same artery also appeared to end in a lymphatic, but though represented as doing so in the diagram I could not be absolutely certain on the point; however, another branch of the same artery could be easily seen with a magnifying lens to end in a vessel which from the translucency and beaded appearance was obviously lymphatic. Again, in Fig. 2 an intercostal artery is seen to give off two small parallel branches which end in a dilatation into which a lymphatic vessel passes in at one extremity and emerges at the other; from this dilatation a short branch passes to another lymphatic vessel. In Fig. 4, again, one of the lower intercostal arteries on the right side is seen to give off three branches which unite together and form a loop from the convexity of which a branch passes off which communicates directly with a lymphatic vessel; from this branch, again, another vessel passes off which terminates in the lowest right intercostal vein; in this case there is a direct communication between an artery and a lymphatic vessel and an indirect one with the lowest right intercostal vein.

FIG. 2.

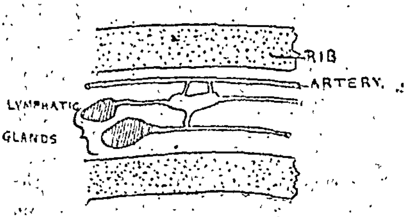

FIG. 3.

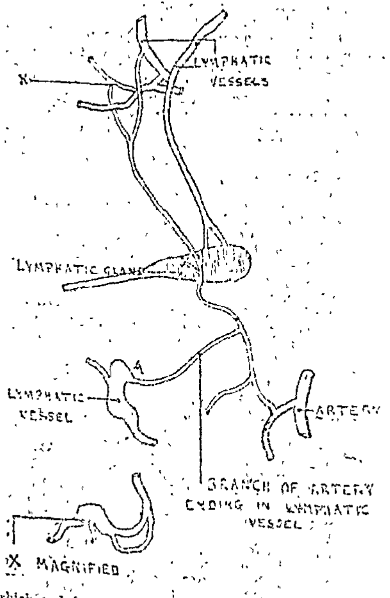

FIG. 4.

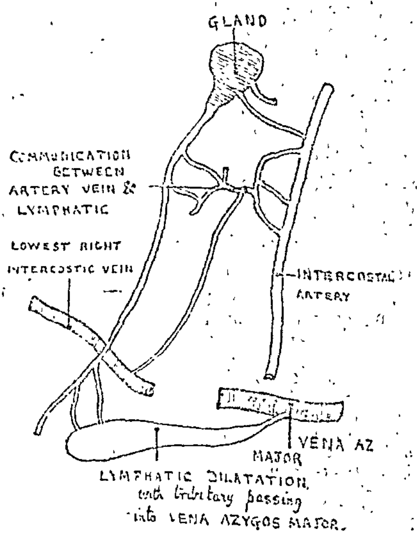


It has been known for some time that the lymph often assumes a pink or reddish hue, and the colour has been shown[3] to be due to the presence of red blood corpuscles. How do the corpuscles pass into the lymphatic vessels? If the fact already mentioned is admitted—viz., that a certain number of small arteries pour their contents directly into lymphatic vessels—the presence of these corpuscles is readily explained, and another factor is present which would materially quicken the movements of the lymph; however, it is only right to add that the arteries apparently do not communicate directly with the lymphatics nearly so frequently as do the veins.

If the communications between the veins and lymphatics can be shown beyond a doubt to take place all over the body—and already they have been observed to exist to a very considerable extent—it follows that we ought to regard the venous system as a part, and that no inconsiderable part, of the absorbent system. We shall then have a ready explanation of certain facts usually regarded as peculiarities in connexion with dissemination of the sarcomata and the carcinomata. It is known that the former usually spread by the veins but sometimes involve the lymphatic glands. The latter invade the lymphatic glands and where secondary deposits are found in the liver, for instance, after carcinoma of the rectum the veins and not the lymphatics are probably the channels through which the cells have passed to reach the liver. It is a fact also that some of the carcinomata, though affecting the lymphatic glands to a slight extent only, yet disseminate rapidly; in such cases it seems hard to believe that the cells have had to traverse innumerable chains of lymphatic glands which, as all admit, act as most efficient barriers before they could pass into the general circulation. A more ready explanation, I would suggest, and one in accord with the facts, would be that the cells had taken, as it were, a short cut into the circulation either by passing along these communicating vessels into the veins or else had passed into the veins by means of the direct continuity which Frohmann pointed out exists between them and the lymphatic vessels in the substance of the lymphatic gland itself.

---

[3] Cyclopædia of Anatomy and Physiology: Lymphatic System by E. Lane, vol. iii., p. 220.

In conclusion, then, I would urge the following considerations. 1. The azygos veins normally receive a great many lymphatic vessels. 2. Some of the smaller arteries in the thoracic region open directly into lymphatic vessels; some of the smaller veins open directly into the large lymphatic trunks; and these two factors help to quicken the movements of the lymph. 3. Direct communications are found to exist between arteries, lymphatic vessels, and veins. 4. The communications between veins and lymphatic vessels have been observed to take place in a great many regions in the body. 5. Owing to the presence of these communications the cells of a malignant growth can pass either from the lymphatics into the veins or *vice versâ*, and hence not only in the sarcomata but also in the carcinomata the veins, as well as the lymphatics, should always be regarded as channels along which the cells may at any moment be conveyed to distant parts of the body.

Wimpole-street, W.

A CONTRIBUTION TO THE SURGERY OF THE KIDNEY.

BY LEONARD W. BICKLE, F.R.C.S. EDIN.,
HONORARY SURGEON TO THE ADELAIDE HOSPITAL, SOUTH AUSTRALIA.

THE interest in Case 1 is of a twofold character. First, as another instance of the toleration of the pregnant uterus to abdominal section; and secondly, the smoothness of the case for the first week and then the febrile disturbance due to the recurrence of a dermatitis to which the patient was subject. The dermatitis in this attack was evidently due to the altered excretory conditions, as dermatitis and temperature alike fell when the urine from the remaining kidney reached a normal amount.

CASE 1. *Nephrectomy during the third month of pregnancy; recovery; subsequent normal delivery of a healthy infant at term.*—The patient, a married woman, aged 29 years, the mother of four children, was admitted into Adelaide Hospital on March 7th, 1898, complaining of pain and swelling in the left side of two years' duration, which commenced with aching pain in the left side and the lower part of the back. A lump was first noticed about three months previously; the pain had increased much and was of a throbbing, burning character, but was not present every day. At times she passed a very large quantity of urine and then the lump or swelling got larger (?). The patient's father had died in hospital from "swollen knee" and her mother had died from "dropsy" after confinement. The patient had been married 11 years and had had four children. She had had one miscarriage two and a half years previously at about the sixth week. She had lost flesh of late. Her appetite was fairly good but she was unable to take food. Resonance and fremitus were normal. The breath-sounds were harsh and dry. The heart was normal and the arteries were healthy. The skin of the abdomen was flaccid, the lineæ albicantes were well-marked. On the left side a tumour which varied in size was to be felt. The patient had dragging pains when she tried to lie on the right side, but none when lying on the left side. The tumour was not to be differentiated from the left lobe of the liver. It was situated under the left costal arch, and though it was not moveable yet it came down with respiration. It measured about four and a half inches vertically and four inches transversely, it was not painful to touch, and was apparently cystic in character. The urine was of specific gravity 1020; it was clear, acid, and contained no sugar or albumin. The skin was very [illegible] and dry and was usually so, especially in wint[illegible]rch 14th the patient complained of much pain. On [illegible] the urine was turbid and contained a small amount [illegible] albumin. The urine had been measured daily, but had not varied much in amount. On the 17th a consultation was held; further observation was advised before operating. On the 27th the tumour had increased in size and could be pushed into the loin; the patient's distress was greater. On the 29th, in view of the increasing size of the tumour and pain and the probability of the patient being pregnant, in further consultation a laparotomy was agreed upon and carried out forthwith. Chloroform was given by Dr. Kinmont. I started my incision from the costal arch at the linea semilunaris and continued it somewhat down and out for two and a half inches. On the abdomen being opened the cyst was found to be retroperitoneal. The incision was extended about one inch. The posterior layer of the peritoneum was cut through and the cyst was exposed. The cyst was tapped and a small amount of clear fluid with a faint urinous smell was drawn off. *Whilst this was being tested the cyst suddenly ruptured.* The fact that the cyst contained no mother or daughter cyst negatived a possible origin—viz, hydatid of the kidney. The thin walls of the cyst and the ready rupturing showed what would have happened later if the tumour had been left and the pregnancy had progressed. *Having thus* a hydronephrosis to deal with it was decided to remove the cyst and kidney rather than to leave a permanent urinary fistula. Accordingly the kidney was brought out and the pedicle was transfixed with a blunt needle and tied with a Staffordshire knot. The vessels and the ureter were re-tied on the face of the stump. No other vessels required tying during the whole operation. The abdomen was then flushed out with boric solution and the wound was closed with silkworm-gut sutures, a glass drainage-tube with a rubber drain being left in the lower part. The upper part of the wound was sealed with Whitehead's paint. The temperature after the operation was 96 8°F. The afternoon temperature of reaction was 101°. There was no sickness for over 12 hours. A small amount of fluid was drawn off. On the 30th sickness and flatulence were a little troublesome and the temperature was 99 2°. The drainage-tube was removed and the stitch which had been left loose was tied. Three grains of subchloride of mercury were given and one ounce of haustus albus in the morning. The urine measured 8 + 6 ounces. On the 31st there was less sickness. The urine measured 8 + 9 ounces = 17 ounces. On April 4th the patient's condition was good, all going well. The wound when dressed was found to be quite healed. On the 7th the patient was not quite so well, complaining of pain in the left side; the temperature was 100°. On the 8th her general condition was about the same; there was some exudation about the stump. On the 10th she was better; her skin was harsh and dry, and there was some dermatitis. On the 12th she had pains in nearly all of her joints and the dermatitis was *very troublesome, preventing sleep. The temperature* was 98·4° in the morning and 100 4 in the evening. Sodium salicylate and sodium bicarbonate were given. On the 16th the temperature was 98 4° in the morning and 103° in the evening. On the 18th the temperature was 99° in the morning and 102·4° in the evening; there was much irritation; the urine measured 21 ounces. The patient was sleepless. It was probable that the whole irritation and trouble were due to want of compensation by the right kidney. One-twentieth of a grain of pilocarpine was given every four hours. On the 19th the temperature was 98° in the morning and 100·6° in the evening. On the 20th the urine measured 43 ounces; the dermatitis was almost gone. The cicatrix was firm and sound. The temperature was 98 4° in the morning and 99 4° in the evening. The uterine enlargement steadily increased. There was no further trouble.

In due course the patient was delivered of a healthy child, the labour being normal in every way. She came to see me some weeks later to show her child who was the picture of health. There was no vestige of ventral hernia. In August, 1899, I heard that the patient was quite well.

CASE 2. *Nephro-lithotomy.*—The patient was a man, 56 years of age, who first consulted me in September, 1891, complaining of pain in his left side of over 12 years duration. In the earliest onset once or twice he had passed blood in his urine, but none since. The pain was aggravated by exertion and at times it was severe. He also complained of localised sweating This was curiously marked The under vest would be quite wet for an inch or two in width round the zone of this pain which was that of the left renal region. The sweating was a great source of discomfort. I have noticed the same localised sweating since then in kidney cases. The urine was clear and pale, giving just a faint ring of albumin with cold nitric acid. Microscopically a few blood corpuscles, leucocytes, and crystals of oxalate of lime were seen. The diagnosis arrived at was stone of the oxalate variety in the left kidney The patient was very loth to accept the diagnosis as he had consulted several other medical men who had not suggested it He was a very bad subject for surgical interference, and as he refused to hear of it a temporising policy was pursued Belladonna locally and lithia citrate internally with an occasional opiate at night until the end of the year rendered life tolerable during 1892 and 1893 He always had the dragging pain, but as he expressed himself, it was bearable, occasionally he came to see me In October, 1894 he had profuse hæmaturia so free that the question of cutting down on to the kidney was discussed By rest and astringents it abated The hæmaturia clinched the diagnosis After this he was occasionally worse and better, still preferring to temporise although told that an operation was the only course In August, 1896 he came saying that life was unendurable He was directed to go home and to bed, and two days later, with the kind assistance of Mr J C Weld and Mr C D G Morier, I cut down on the kidney by the usual lumbar incision No stone could be felt by the finger, but after the systematic use of the searcher a stone was struck, the kidney was incised, and with some difficulty the large stone here figured was removed The hæmorrhage was very profuse, so the wound was closely packed and the patient was made comfortable A few days after the operation a small nucleus of oxalate was passed Convalescence was a little retarded by some infiltration of urine into the tissue of the back, necessitating free incisions From the tenth to the seventeenth day after the operation his mental condition was very serious (an afebrile delirium) but after the seventeenth day he recovered rapidly On the twenty seventh day urine ceased to come from the wound, he had then been up in a chair for some few days

His recovery has been complete and from being a man prematurely aged, of slow, bent gait and generally depressed condition he is now (three years after the operation) a fairly brisk, cheerful man to whom life has ceased to be a burden

The accompanying illustrations give a good idea of the stone and of its actual size It was clearly an oxalate with some deposit of phosphates, it weighed rather over 240 grains It is not a little remarkable that so large a stone should only have produced one serious attack of hæmaturia, that attack occurring two years before the removal

Two aspects of the stone

Adelaide

HALLUX VALGUS AND HALLUX VARUS[1]

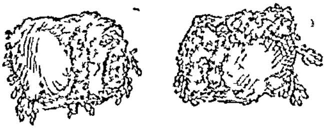
BY J JACKSON CLARKE M B LOND, F R C S ENG,

SURGEON TO OUT-PATIENTS AT THE NORTH-WEST LONDON AND CITY ORTHOPÆDIC HOSPITALS

Definition of terms —The fact that in Latin the terms "valgus" and "varus" were used inversely to the manner in which we use them need hardly be made the subject of discussion, since their misuse has become so well established that their meaning is never in doubt When it is desired to express accurately the nature of the deformity some careful consideration of the meaning of words is desirable In different languages the terms "abduction" and "adduction" as applied to the great toe are used in opposite ways thus Hoffa defines hallux valgus as an "Abductionstellung" of the great toe Redard terms it "outward deviation" of the great toe but uses the terms "adduction" and "abduction" in the same sense as Hoffa—that is, conversely to their employment by English anatomists Perhaps it will be simpler to follow the continental fashion in this matter and make the meaning of the term "abduction" clear by adding the qualifying phrase "from the median sagittal plane of the body" There is in hallux valgus something more than this and I should be inclined to suggest as the complete definition the following —Hallux valgus is a deformity in which the great toe, when the foot is at rest, assumes a position of abduction from the mesial sagittal plane of the body and at the same time is, to a greater or less extent subluxated outwards, it being understood that normally the great toe lies in the same plane as the first metatarsal bone Hallux varus is the condition converse to hallux valgus

Anatomy —The internal lateral ligament is elongated sometimes thicker, sometimes thinner, than normal With the outward displacement of the base of the first phalanx there is a corresponding outward displacement of the sesamoid bones and the flexor, extensor and other tendons The cartilage of the inner part of the head of the first metatarsal bone tends to undergo fibrous metaplasia, and an adventitious bursa to form between the internal lateral ligament and the skin over the exposed inner part of the head of the metatarsal bone In persons suffering from rheumatoid arthritis or gout the anatomical changes of these conditions, separately or combined, are present In rheumatoid arthritis there is I believe, constantly a groove denuded of cartilage and lined by rarified bone, the groove is caused by the pressure of the inner margin of the base of the first phalanx Extensive villous overgrowth of the synovial membrane may be present in the same class of case, and I have also observed both in operating and in making post-mortem dissections that in rheumatoid cases the internal lateral ligament is usually thin and often allows the adventitious bursa to communicate with the joint cavity The changes in the heads of the metatarsal bones as seen in a case which I have previously reported to the British Orthopædic Society are shown in Fig 1.

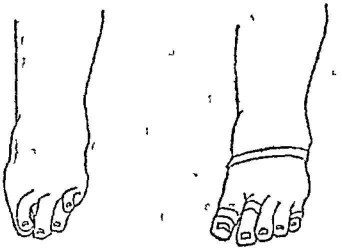
FIG 1



The anterior surfaces of the heads of the metatarsal bones removed for hallux valgus in a case of rheumatoid arthritis

Causation —Congenital hallux valgus, though far less common than acquired is met with from time to time I can recall three instances that have come to my notice in the past three years One was that of an infant a few days old In this case there were about 40 degrees of hallux valgus, the second toe was displaced upwards above the great toe, and the little toe was displaced inwards upon the dorsum of the foot, as shown in Fig 2 The toes were

FIG 2



The left foot of an infant with congenital hallux valgus &c and (to the right) the same foot with the deformities corrected by strips of adhesive plaster readily replaced and retained in their normal positions by strips of strapping. The second case in which the deformity was said to have been present at birth came to my notice when the patient was 14 years of age. The second toe was a hammer-toe of the common type and the little toe was deformed in the same way as in the first case. The third case was admitted into the City Orthopædic Hospital under the care of Mr. Poland, who operated, and who, I hope, will record the nature and result of his operations. I have no doubt that these cases are of mechanical origin and, like congenital club-foot, are due to accidental cramping in utero.

---

[1] Introduction to a discussion at the meeting of the British Orthopædic Society held on Feb. 17th, 1 00.

ACQUIRED HALLUX VALGUS.

Much has been written about this very common deformity and various categories of causes have been adduced. Thus, according to Redard, we have the following theories:—1. The muscular theory—e.g., Nélaton attributes it to contraction of the extensor proprius hallucis; Duchenne to paralysis of the adductor (*Anglice*, abductor) hallucis; and Dubreuil to predominance of the abductors over the adductors. 2. The ligamentous theory. According to Malgaigne the deformity should be regarded as the effect of softening of the internal lateral ligament of the joint. 3. The mechanical theory. Broca appears to have been the first to recognise the part played by badly shaped boots and shoes in the causation of hallux valgus; I believe that tight socks will sometimes occasion the condition in young children. Redard on this head observes: "I admit that boot pressure, though not an efficient, is an occasional cause. How, in fact, can we explain the occurrence of hallux valgus in persons who have never worn boots or at any rate tight ones?" 4. The osteo-articular theory. Verneuil counts everyone who has hallux valgus to belong *ipso facto* to the arthritic class. He found that 50 per cent of the patients had rheumatoid arthritis. My own investigations which were made when I was pathologist at St. Mary's Hospital upon some hundreds of such joints would give a still larger percentage. On closer examination these theories resolve themselves into a simpler statement. Paralysis of the adductor (*Anglice*, abductor) hallucis apart from that of the other muscles I have not observed, but it may occur and would give rise to hallux valgus. Of the remaining theories the second becomes part of the fourth, for softening of ligaments apart from traumatism or extension of inflammation from the superficial tissues is only seen in some bone and joint affections. Thus the case may, I would submit, be stated thus:—Hallux valgus acquisitus is usually due to certain predisposing causes acting together with an exciting cause. The predisposing causes are such as cause weakness of muscles and softening of ligament and bone—e g, gout, rheumatoid arthritis, traumatism, and rickets. The commonest exciting cause is badly-shaped boots or shoes

Sex incidence—Women are more commonly affected than men, probably, I would suggest, because they are more often influenced by stupid fashion in boots and their muscles are less powerful to oppose the deforming effect of boot-pressure

Symptoms—Lameness arises when the deformity is pronounced and is due to pain in the first metatarso-phalangeal joint, to the loss of the action of the great toe in walking, and to concomitant deformities. The latter deserve separate notice.

Concomitant deformities—Ordinary flat-foot and transverse flat-foot with or without metatarsalgia are naturally common because the same predisposing causes contribute to them as to hallux valgus. The outward displacement of the long flexor of the great toe and of the transversus pedis muscle may also help in producing the two forms of flat-foot in cases where the hallux valgus precedes the other deformities in point of time. Some of the concomitant deformities follow the outward wheeling of the great toe as direct results; all four remaining toes may be displaced outwards, their abduction being usually accompanied by some extension of their metatarso-phalangeal and flexion of their interphalangeal joints. This may attain such a degree that they have the characters of hammer-toes The second toe is most commonly affected to this more severe extent. In severe cases of hallux valgus the second, third, and fourth toes may lie upon the great toe Less commonly the second and third toes lie beneath the displaced hallux. Davies-Colley has expressed the opinion that many cases of hallux rigidus become converted into hallux valgus. I have not as yet observed this myself.

Treatment.—General treatment is often of the first importance and the aid of the physician is required. Careful regulation of the diet and the use of guaiacum and internally are most frequently called for. The treatment the surgical accidents—e.g., suppuration—hardly concerns us in the present discussion. Prophylactic treatment includes allowing children to walk with bare feet as much as possible and providing them with roomy socks and properly boots. I need not here go into detail on the latter point; but I may say that I think the rules laid down by von Meyer may always be followed. Gymnastic treatment, active adduction exercises, and Ellis's tip-toe exercise are all useful; passive manipulations, douching, and massage, are also of use. As to mechanical treatment, in slight cases bandages made on the plan described by Sayre, together with the foregoing measures, may suffice. I find that many patients can be taught to make efficient bandages of webbing for themselves. The septate boot treatment is an idea which originated with von Meyer and which has been well worked out by G. R. Fowler The "toe-post" has recently somewhat displaced it in this country. I have tried this latter device in a fair number of cases but save in slight degrees it has proved unsatisfactory. Mr. Luke Freer's instrument, which I think might be termed a "toe lever," certainly promises better things and we shall hope to hear his further experience of it. A simple device ascribed by Hoffa to Mr. Noble Smith consists in surrounding the great toe by a leather band to the inner side of which is attached a string which is passed through an aperture in the inner border of a correctly shaped boot-sole. Beely has so arranged the same device that the aperture in the sole does not communicate with the exterior. Sole-plates, whether of leather or metal, are often of use. Some are designed to be worn inside the boot, the toes being fixed to the plate by tapes. This method amounts to wearing a sandal inside a boot. Where the hallux valgus is complicated by the presence of deformities in other toes this plan is sometimes required, but when the deformity of the great toe is the only condition requiring treatment the sole-plate may, in my opinion, be conveniently dispensed with in favour of a lever as described below. For use at night, especially after operations, a well-made sole-plate with a good heel-piece, ankle- and instep-straps, as well as toe-straps is often to be recommended. This appliance, like all other instruments, should be carefully designed by the surgeon. The familiar "bunion spring" of the late Mr. Heather Bigg, sen., is so well known that I need not here describe it. Springs may also be added to the metal sole-plate. I think that the simpler rigid apparatus is preferable to springs. The mechanical device of the lever is the one I most commonly use. The instrument consists of a thin, flat band of steel shaped to lie under the great toe, to curve outwards to avoid the head of the first metatarsal bone, and to end in a second straight piece which lies under the hollow of the arch of the foot. The fulcrum is a padded metal projection jointed to the front of the hinder straight piece and working on the inner side of the metatarsal bone just behind the head. A strap is attached to the posterior end of the lever to pass in a figure of 8 round the ankle and to be fastened off at the fulcrum. A second strap may be added passing round the forepart of the waist of the foot. The toe is attached to the front arm of the lever by a leather loop. This arrangement can be worn inside the boot and most patients can also bear it at night. In some, however, the pressure of the fulcrum interferes with sleep and in such cases I recommend a sole-plate for night use.

Operative treatment.—Tenotomy, syndesmotomy, osteotomy, partial and complete excision of the head of the metatarsal bone, and excision of the base of the first phalanx have all been employed My own experience is limited to partial excision and complete excision of the head of the metatarsal bone. Of these two operations I now usually adopt the latter; firstly, because there is less pain immediately after the operation, and secondly the shortening of the great toe diminishes the tendency to return of the deformity. The incision which I have used is a longitudinal one at the supero-internal aspect of the joint. The head of the bone is readily removed either by a chisel or a Gighli's saw. The internal lateral ligament can be shortened and fixed by one or two cat-gut stitches and the *bursa*, villous growth, and synovial membrane generally can be removed. Hæmophilia, diabetes, defective kidneys, and broken-down constitution are the chief contra-indications to operative interference.

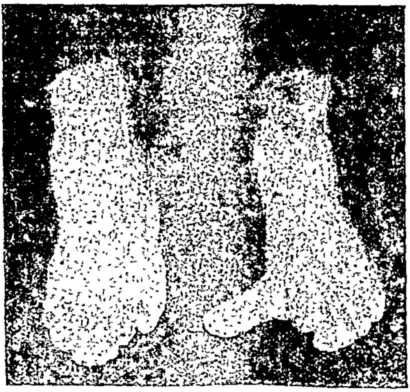
HALLUX VARUS.

Hallux varus, as already stated, is the converse of hallux valgus. Some confusion has arisen by certain authors using the term "hallux malleus" as a synonym. The chief characteristic of hallux malleus is pronounced flexion at the metatarso-phalangeal joint and such flexion is combined with adduction of the great toe in some cases of hallux varus; when this is the case it would, perhaps, best be described as "hallux varus et malleus." The congenital hallux malleus observed by Nicoladoni to become complicated in after-life by flat foot may in some cases present a certain degree of hallux varus in the original deformity.

Hallux varus may occur congenitally either alone or as part of the deformity of congenital equino-varus. In the latter condition if treatment is begun at the proper time—i.e., soon after birth—the deformity is always cured. Hallux varus has been noted in cases of congenital absence of the fibula. No case of pure congenital hallux varus has come to my notice, but I should anticipate that persistent careful bandaging would remedy the condition.

Hallux varus in dichotomy of the great toe.—A set of four casts in the museum of the City Orthopædic Hospital were taken from a patient under the care of the late E. J. Chance. The feet before operation had each six digits, as in Fig. 3 to the right, the innermost being in the position of hallux varus. In such cases removal of the innermost toe is all that is required, and Chance's case shows that the result is highly satisfactory.

FIG. 3.



To the right a cast of a foot with dichotomous hallux, the innermost digit being in a state of hallux varus; to the left a cast of the same foot after amputation of the innermost digit.

Acquired hallux varus.—The records are very scanty on this head and I must confess that I have no personal experience to give. It occurs in some cases of severe genu valgum. In certain paralytic and traumatic cases this deformity would probably arise.

In conclusion I would venture to state my opinion that every case of hallux valgus is curable. The most troublesome cases are those in which a second hammer-toe has been (quite unnecessarily) removed previously to the patient being seen.

Old Cavendish-street, W.

A CASE OF LEPROSY.

BY JOHN D. GIMLETTE, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENCY SURGEON, PAHANG, MALAY PENINSULA.

MANY clinical cases of leprosy have been published, but the simple example here recorded is of general interest. The patient was an unmarried Eurasian, aged 27 years. He was born in Singapore but had lived for some time in the Malay Native States. He was a clerk and interpreter in the police-court at Pekan. There was no case of phthisis in the family as far as was known. One sister suffered from "fits." His father and brother were alive and well. The mother had died in child-bed. The patient had had the ordinary ailments of childhood, but otherwise had been in fairly good health until about Christmas, 1894. He was then treated at Pekan for "simple rheumatic inflammation of the tendon sheaths with some degree of high temperature and glandular swellings." In March, 1896, this illness recurred and was accompanied by a curious bilateral purpuric eruption on the legs fugitive in character. There was again acute inflammation of the tendon sheaths of both feet and of the right hand. He was sent to Singapore, where he was found to be suffering from a peripheral neuritis which was diagnosed as beri-beri. About this time the legs were swollen and he was unable to walk. At the end of June, 1896, he returned to duty. He said that he had squandered his money ever since in the purchase of useless, empiric drugs, but that he had never felt himself again. During the last two years he had had attacks of dysenteric diarrhœa and had been gradually losing heart and strength.

When I saw the patient he complained greatly of weakness and said that his legs often felt useless, especially after walking. He had a rash which came and went. It was on the face, the legs, and the arms. It was not painful and did not itch. About six months previously sores broke out on his fingers, which healed up from time to time of their own accord. Four or five months previously he felt a small lump on the nose. It had given little or no inconvenience and had remained about the same size. He noted that he fumbled in dressing himself and could not button his clothes with ordinary precision For some time he had had a chronic cold and had snuffled, but he had had no cough. The appetite was indifferent, the teeth were decayed, and the bowels were irregular. On examination he was found to be a tall, thin, sad-looking man with an unnatural aspect. The skin of the face was coarse, with a livid flush on each cheek. The ears were enlarged, projecting, and deformed and were wrinkled and nodular. At the bridge of the nose there was a small broad tubercle. The eyebrows were scanty. The hands were wasted as if from paralysis of the ulnar nerve and the fingers showed clearly some trophic lesions in the skin. They were covered with dry sores, especially on the back of the phalangeal joints. Otherwise the skin here was smooth and glossy as if it had been varnished. There was impairment of sensation in the skin of the fingers and forearms and in places there was anæsthesia. The muscles of the arm and especially those of the forearms were wasted. The interossei muscles were atrophied and doubtless an application of the Roentgen rays would already demonstrate atrophy of the metacarpal bones. The body generally was covered with large patches of brownish pigmentary stains. The chest was ill-developed, but the heart and lungs appeared to be normal. On the outer side of each leg there were patches of anæsthesia with purplish eruptions on the shins. A distinct nodule, among others, of about the size of a split pea could be felt on the extensor aspect of the right leg. The patient was sent to Singapore where he was seen by Dr. M. F. Simon, in consultation with Dr. J. T. Leask and Dr. W. G. Ellis. They found the bacilli of leprosy in large numbers in the discharge from a sore on the finger and in serum taken from a nodule on the ear.

I have much pleasure in expressing my thanks to the Principal Civil Medical Officer (Dr. Simon) for his kindness in confirming the diagnosis. There were no other cases of leprosy in Pekan at the time. The disease, in fact, is not common in Pahang, where it is usually met with among the poor of the native population. In this case, however, the patient was an intelligent member of the community following a public occupation and leading a more or less healthy life. It is an instance of the mystery which still surrounds the origin of isolated cases of leprosy. The history is of special interest now that the compulsory segregation of lepers is under the consideration of the Government.

It is agreed that leprosy is a contagious disease. All observers, however, who are not influenced by any theory and who have no desire to fit the facts of their cases to any favourite doctrine will, I think, admit that a certain number of cases appear to militate against a very widely received opinion as to the advisability of compulsory segregation. Ample as the reason for legal measures may be in the colonies, they will, I think, allow that under certain circumstances voluntary isolation is a sufficient safeguard. I refer especially to those periods of latency which may occur during the course of the disease.

In the case given above the patient had given up his occupation and had made no attempt to trifle with his affliction. If any inquisitorial interference with his home had been instituted there would not have been wanting critics to designate it as a grave offence against the public liberty. Doubtless if the disease had been found out earlier he would have been discharged from his office long before. It may be fairly presumed, however, that until the open sores had developed he had not been an immediate source of danger to the crowds in the police courts. After that time the danger from inoculation would have been great. In this particular case the difficulties in diagnosis of the early stages of leprosy were well exemplified. It was at first confounded with an infective form of rheumatism and then with the peripheral neuritis of beri-beri. Later the patient was popularly supposed to be suffering from tertiary syphilis. Like hydrophobia and diphtheria leprosy is most deadly when it forms a focus, and although the bacillus so closely resembles that of tuberculosis the resisting power of man to the bacillus lepræ is probably not as great as that to the tubercle bacillus. In both cases isolation as a preventive measure affords the best and only protection for the public health, and although the hygienic treatment of tuberculosis in sanatoria seems likely to repay at last the persevering quest of modern scientists the cure of the individual leper seems more likely to be brought about by the inoculation of some antitoxin.

Kuala Lipis, Pahang, Malay Peninsula.

A CASE OF SUPPRESSION OF URINE OF 60 HOURS' DURATION TREATED BY OPERATION.[1]

BY FRANCIS JAFFREY, F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

A MAN, aged 53 years, was admitted into St. George's Hospital on Dec. 3rd, 1899, complaining that he had not felt well for several weeks. During the last week of November he suffered from pain in the left loin and a dragging sensation in the region of the left kidney. Micturition was frequent, his urine appeared natural in colour, and he had never seen any blood. On Dec. 1st he was unable to pass any urine whatever and complained of acute tearing pains in the left groin and lumbar regions with frequent vomiting. He was seen by a physician, under whose directions hot fomentations were applied to the loin and diuretics given internally, but with no good result. The suppression persisted during the next two days A catheter was passed, but only a little blood-stained mucus was drawn off. No definite tumour could be felt at first, no doubt owing partly to the thickness of the abdominal walls and to their rigidity, but on the 3rd a very definite tumour could be felt which was thought to be a distended kidney, probably hydronephrosis. He had never had any trouble with his urinary tract and apparently his only illness was an attack of congestion of the lungs when he was much younger.

On his admission to the hospital, when I saw him on the evening of Dec. 3rd, 60 hours from the onset of the total suppression of urine, he appeared to be healthy. He was a somewhat stout man. His expression was anxious and he was restless. There was marked perspiration, especially of the hands, and the tongue was fairly moist. The pulse was rapid (124) and intermittent, dropping a beat about every seventh beat, and the respirations were 24. He complained of considerable pain and tenderness over the region of the left kidney There was marked resistance of the abdominal walls on the left side, but by careful palpation a large rounded swelling could be felt, about as large as a cocoanut, soft, though no actual fluctuation could be made out. The manipulation appeared to cause much pain, so it was not continued. A catheter was now passed, but only a little blood-stained mucus was removed; I therefore recommended an exploratory operation by a lumbar incision and draining the supposed hydronephrosis.

Gas and ether were given and an oblique incision six inches long was made in the left lumbar region. Upon opening the swelling it was found not to contain urine, but blood-clot and serum to the quantity of rather more than a pint, which was situated between the perinephritic fat and the kidney, and on incising the capsule blood was found between the capsule and the cortex. The capsule being stripped off the kidney over a considerable area the kidney appeared to be larger than normal, and on incision it was much congested and bled very slightly. The pelvis of the kidney was full of blood-clot. No calculus was felt. A sound was carefully passed into the upper part of the ureter but nothing was felt. The pelvis of the kidney and the space outside the kidney were freely irrigated with warm water at a temperature of 102° F. A large-sized drainage-tube was passed into the pelvis of the kidney and the wound was sewn up with silkworm-gut sutures and dressed with cyanide gauze and wool. Two hours later the dressings had to be changed as it was found that urine was being freely secreted and passing from the drainage-tube. During the night the drainage-tube slipped out of the pelvis of the kidney and I did not think it necessary to replace it.

Thirty-six hours later practically all the urine was passed by the urethra. The first urine passed contained blood but not in any great quantity, the following day it was only slightly turbid, and before the end of the week there was no blood. The urine was pale in colour, of a specific gravity of 1015, it was faintly acid, and there was no albumin. The quantity passed in 24 hours was 65 ounces, and the quantity increased daily during the next fortnight till it reached 100 ounces in the 24 hours and the following week it gradually diminished to 70 ounces. The intermittent condition of the pulse disappeared during the patient's stay in the hospital. The stitches were removed on the sixth day and on the sixteenth day he was allowed to get up He left the hospital just three weeks after admission, quite well.

This case is one of considerable interest—firstly, as to the cause of suppression; secondly, as to the question of operation in similar cases; and, thirdly, with regard to the question which has recently arisen regarding the insurance of the lives of patients after operation.

As to the cause of suppression of urine it may be placed under two heads (1) obstructive suppression due to some mechanical cause, and (2) non-obstructive suppression due to a pathological cause. It is difficult to know in which class to place this case In obstructive suppression the usual cause is an impacted calculus either in the pelvis of the kidney or in some part of the ureter, the other kidney not being functionally active or being so diseased that it is unable to carry on the increased amount of work. I can recall a case very much resembling the above. Some years ago I was called to see a case of total suppression of urine, but when I saw the sufferer operative interference was out of question, the patient being already moribund. At the post-mortem examination the capsule of the kidney was completely stripped off up to the hilum and contained a pint of blood-clot, the kidney was enlarged, and on cutting into the pelvis of the kidney a scale-like piece of calculus was blocking up the ureter. The very slightest manipulation would have displaced it. The opposite kidney was totally obliterated and its place was taken by a large branched calculus covered by only the capsule. It is quite possible that the present case was of a similar nature and that the irrigation displaced the calculus thereby allowing the free passage by the ureter. Of course, it is quite possible that the suppression was due to kinking or pressure of the ureter by the blood surrounding the kidney. Of likely causes of non-obstructive suppression the only one is congestion of the kidney. The patient admitted that he had been dieting himself with the view of reducing his weight—in other words, he had been "Banting"—and in a patient over 50 years of age this might easily have caused marked congestion and thereby suppression.

As to the question of operation in these cases I am of opinion that if one is certain of the diagnosis the sooner the kidney is explored the better. There is a difficulty in many cases of ascertaining which kidney is affected Laparotomy and the examination of both kidneys have been recommended followed by a lumbar incision and the removal of the stone, but there are many cases recorded which have been operated upon and in which no stone has been found. Some authors place the number as high as one case in every five where no stone is found but after the operation all the symptoms of stone disappear. Is not this due to relief of tension? Mr Reginald Harrison[2] in his address before the Medical Society of London and in THE LANCET[3] advocates renal puncture in cases of kidney tension, and he quotes several cases which were benefited by operation after which the hæmaturia, the albuminuria and the severe pain disappeared Dr David Newman of Glasgow[4] has published a very interesting series of cases of occasional suppression of urine treated by operation with complete recovery from all the symptoms and he also is of opinion that these cases were due to increased vascular tension in the kidney The case which I have now brought forward is much more severe than any case quoted by either of these authors, both as to the length of time of the total suppression and of the condition of the kidney and the parts around it I certainly feel inclined to recommend operation where the ordinary medical treatment has failed after a reasonable trial

---

[1] A paper read before the Harveian Society of London on Feb 15th, 1900.

Now, as to my last point that of insurance of patients after an operation on the kidney This patient applied to an insurance company but was told to wait three months Apparently his only trouble was an intermittent pulse, but before the three months were up he developed suppression of urine and when he recovered he again re applied but they refused to insure him at any price I should like to know whether this man's life is less valuable now than it was before the operation? I am inclined to doubt it The same question might and probably does, occur with much younger patients

MIDDLESEX HOSPITAL

A CASE OF PREGNANCY COMPLICATED BY FIBROUS TUMOUR OF THE SUPRA AND INFRA VAGINAL CERVIX, ABDOMINAL HYSTERECTOMY, OPERATION, RECOVERY

(Under the care of Dr WILLIAM DUNCAN)

A MARRIED woman, aged 38 years, was admitted into Prudhoe Ward of the Middlesex Hospital on June 1st 1899, complaining of excessive loss of blood and of a lump in the abdomen There was nothing to note in the family history of the patient The catamenia began when she was 12½ years of age they were regular every three weeks, lasted for three days and were always accompanied by pain and headache until after the birth of her first child The last period had ended seven days before admission She was married 19 years previously and had had 10 children, four of them were alive and healthy and six had died from convulsions between the ages of three weeks and 12 months She had had three miscarriages at three months the cause of which was not known The patient had had a miscarriage 18 months previously and since then the periods had been excessive, sometimes lasting three or four weeks and being accompanied by clots The patient said that at times she had lost a large quantity of blood She had noticed a lump in the right side of the abdomen for the previous two years and thought that it had only got slightly larger Micturition had been frequent but not difficult or painful and the bowels had been regular She thought that she had been getting thinner for the previous two years

On admission the patient was found to be a fairly healthy looking woman The cardiac respiratory, and urinary systems were healthy Her appetite was bad, she had no pain after taking food, and she occasionally felt sick (but did not vomit) at no particular time of the day The tongue was furred Examination showed that the abdomen was somewhat distended by a smooth, firm, elastic tumour reaching up to the umbilicus and inclining more to the right side The tumour was fairly mobile but movement caused pain, no intermittent contractions could be felt It was dull on percussion and both flanks were resonant Auscultation revealed a loud uterine souffle but no fœtal heart sound The breasts were not enlarged but the veins crossing over the chest were prominent and the areolæ were somewhat deeply pigmented Some secretion could be squeezed out of the right nipple Vaginal examination under anæsthesia revealed a soft round red tumour filling the upper half of the vagina and apparently springing from the posterior and left side of the cervix on which sides it was closely adherent to the vaginal wall, indeed, it seemed to be growing in the vaginal wall, in front, high up, the finger tip could just reach the os uteri The tumour was continuous with the abdominal tumour and moved with it The sound was not passed The tumour was so soft that a volsellum forceps tore it and caused free bleeding, this was controlled by a silk suture and iodoform gauze packing

Dr Duncan said that the case was evidently one of a soft fibroid (possibly sarcomatous) growing from the supra vaginal cervix down into the vagina and involving the vaginal wall He thought that the patient was pregnant and that the uterine body was probably also myomatous It was evident that the only way of dealing with the growth was by performing total abdominal hysterectomy The operation was performed on June 22nd Gas and ether having been administered an incision extending from the umbilicus to the pubes was made and the abdomen was opened A bluish red tumour presented which was evidently a gravid uterus as the fœtus could be felt floating in the liquor amnii The tumour (which corresponded to about a five months gestation) was drawn out of the abdomen Then the right broad ligament was transfixed, tied in two places and divided, next the divided layers of the broad ligament on the uterine side were separated by the finger down to the cervix until the uterine artery was felt pulsating An aneurysm needle armed with silk was carried round the vessel, then after withdrawal of the needle the silk was firmly tied and thus both the uterine and ovarian vessels were secured on the right side By a similar procedure the vessels were secured on the left side Next a scalpel carried right round the uterus (about two inches above the attachment of the bladder) made two flaps of peritoneum only, these were stripped off right down to the cervix The anterior flap was carefully dissected down close to the uterus until the finger of an assistant, which was pushing up the anterior fornix per vaginam, was laid bare The vaginal roof was next transfixed piece by piece tied with silk and divided close to the uterus right round until the mass was free As the tumour was intimately adherent to the vagina on one side some of it had to be cut away during removal All bleeding points were next secured then the ligatures (one end of each having been left long) were pushed down into the vagina and this cavity was stuffed with iodoform gauze the cut surfaces of the vaginal roof were then brought together with fine silk, and lastly the peritoneal flaps were brought accurately together by a continuous Lembert's suture During the whole of the operation the intestines were covered up by a large flat sponge which was inserted after the abdominal cavity had been opened This sponge was now removed and the opening was closed in the usual way—(*a*) by continuous fine silk suture for the peritoneal edges, (*b*) by interrupted silk sutures for the edges of the rectal sheaths, and (*c*) by continuous silk suture for the skin The wound was dressed with a strip of iodoform gauze, then a pad of blue wool which was held in place by a many tailed flannel binder The patient stood the operation well, her pulse being of good volume and 100 per minute

The subsequent progress was good The bowels were opened by an enema on the seventh day and the superficial stitches were removed, the wound being perfectly healed There was a rigor of 10 minutes duration on the fourth seventh and eighth days but the temperature and pulse only increased slightly, there was nothing to account for the rigors and the patient said that she had been subject to similar attacks for seven or eight years On July 14th (the twenty second day after the operation) there was a good deal of purulent vaginal discharge and several ligatures were removed from the vagina On the 29th there was very little discharge. All the ligatures except one had come away; the patient was able to get up and said that she felt well. On August 14th, as the remaining ligature showed no signs of coming away, it was removed under anæsthesia. On the 21st the patient was discharged well.

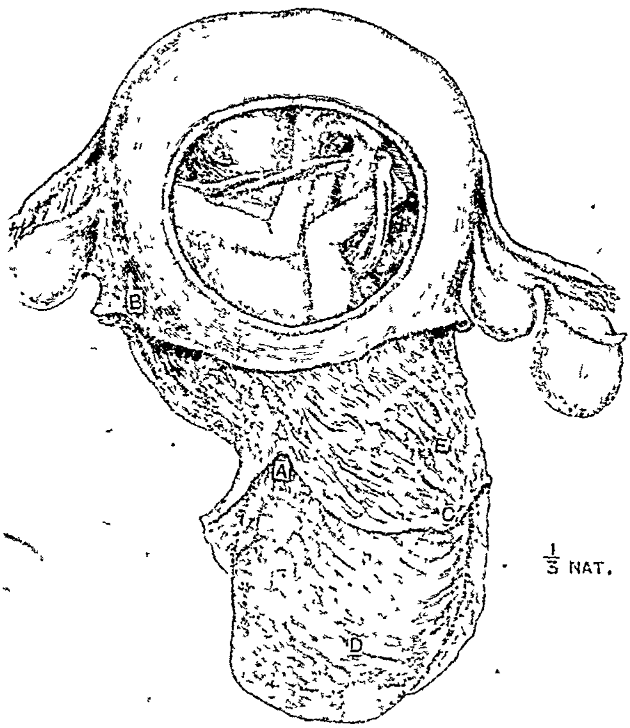
[4] Renal Cases Maclehose and Sons.

Remarks by DR. DUNCAN.—This case is a most interesting and unusual one. In the first place, although fibroids of the cervix uteri are not very uncommon it is in my experience extremely rare to find the growth as it fills the vagina being intimately adherent to the vaginal wall. On a cursory examination the tumour might have been mistaken for a fibroid polypus which had been extruded through the os uteri—indeed, I believe the case was sent into the hospital as such—but careful examination under anæsthesia revealed its true nature. Then with regard to the abdominal tumour one might well be excused for diagnosing it as being a soft myoma of the uterine body, especially as the patient had noticed a lump in her abdomen for a couple of years. On palpation, however, the feel of the mass was more like that of a gravid uterus, and although the patient had metrorrhagia instead of amenorrhœa and there was no morning sickness nor were intermittent contractions felt, still I came to the conclusion from the state of the breasts and the feel of the mass that it was a case of pregnancy complicated by fibroids of the body and cervix uteri.



A, Os uteri externum B, Cut edge of peritoneum on anterior uterine wall. C, Cut edge of vaginal reflection pushed down. D, Vaginal portion of tumour E, Supra-vaginal portion of tumour.

The treatment clearly resolved itself into that of total abdominal hysterectomy even if (as proved to be the case after operation) the fibroid was limited to the cervix, as on most careful examination under anæsthesia I could not satisfy myself that it was feasible to remove the mass per vaginam with safety to the patient. As regarded the proper time to operate the question arose, Should the pregnancy be allowed to go on to near full term, as then at the time of operation the child's life could be saved? I decided against this and in favour of immediate operation on three grounds: (1) at the end of pregnancy a woman is in a most unfavourable state of health for recovery after what would necessarily be a prolonged operation; (2) she would have continued to lose blood for several months before the operation; and (3) the possibility of the tumour being of a sarcomatous nature (this happily proved not to be the case). At the time of the operation the only difficulty experienced was in separating the tumour from the vaginal wall, as one had to be extra careful not to include the ureter in one of the ligatures. To my mind, total abdominal hysterectomy (so-called panhysterectomy) can never be so easy or anything like so safe an operation as abdominal hysterectomy with intra-peritoneal treatment of the stump of the cervix. In the case just recorded, however, there was no alternative but to remove the entire uterus.

The whole subject of "the modern treatment of uterine fibroids" is so extremely important and as such erroneous views as to the mortality of hysterectomy for fibroids have been recently promulgated it is my intention (with the kind permission of the Editors of THE LANCET) to publish in a week or two a paper with the above title. I may here mention that in 1897 I published in THE LANCET[1] a paper giving 18 consecutive cases of abdominal hysterectomy for fibroids, being all the cases which I had operated on up to then, with one death which occurred suddenly from pulmonary embolism 18 days after operation when the patient was convalescent and about to leave the hospital, so that I think the death might fairly be put down as *not* due to hysterectomy. Since the publication of my paper I have performed the operation 50 times with three deaths, so that my results up to now are as follows: in private practice, 21 cases with no death; in the Chelsea Hospital for Women, 22 cases with no death; and in Middlesex Hospital, 25 cases with four deaths; which gives a mortality (if I exclude the death from embolism) of about 4½ per cent. It is to be noted that my four fatal cases occurred in a general hospital. As a matter of fact I have not had a single fatal case *from any operation* in my private practice since August 11th, 1895 (four years and six months), or in the Chelsea Hospital for Women since Oct. 8th, 1897 (two years and four months).

The only correct method of arriving at the true mortality of any operation is to take the results of those who have performed the particular operation a good many times and not to lump together the results of numerous operators, some of whom with only one or two operations may have a mortality of 100 per cent. In an interesting address entitled "Some Points in the Natural History of Uterine Fibroids"[2] Dr. F. H. Champneys has fallen into this error and makes the average mortality from abdominal hysterectomy for fibroids to be 17 per cent. At St. Bartholomew's Hospital the mortality was 27 per cent, or if he had only included the cases up to the end of 1898 (as at the Samaritan and Chelsea Hospitals) the mortality at St. Bartholomew's Hospital would be actually over 31 per cent.—a truly dreadful mortality and one which would render the operation of abdominal hysterectomy absolutely unjustifiable except in the rarest cases. Like Dr. Champneys, I made exactly the same mistake in 1885 when I read a paper before the Obstetrical Society of London on extirpation of the uterus for cancer. With misguided zeal I collected all the cases I could find which had been published both in our own and foreign countries in which the uterus had been removed either through the abdomen or per vaginam, and in my statistics the mortality for abdominal hysterectomy worked out at 72 per cent. and that for vaginal hysterectomy at 28 6 per cent. Doubtless the percentage was altogether wrong; at the present time I suppose most observers would agree that the mortality from vaginal hysterectomy does not exceed 5 per cent., and in my opinion the average mortality from abdominal hysterectomy for fibroids is not more—possibly less—than this.

ERRATA.—In the case of bubonic plague treated with large doses of carbolic acid, as described in THE LANCET of Dec. 9th, 1899, p. 1589, the words "six ounces" on line 50 should be "one ounce"; 12 grains of carbolic acid were given for a dose, not two grains.

TORQUAY HOSPITAL.—The annual meeting of this institution was held on Feb. 15th under the presidency of Mr. R. Mallock. The medical report showed that 359 in-patients had been admitted, against 366 in 1898. The expenditure amounted to £2127 and there was an adverse balance of £382. The committee decided that the honorary medical staff should form a council for the consideration of all professional subjects connected with the hospital and that all by-laws, &c., proposed by them should be subject to revision and confirmation by the board of management.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Acute Ménière's Symptoms in Leucocythæmia.

A MEETING of this society was held on Feb. 27th, Dr. G. FIELDING BLANDFORD, the Vice-President, being in the chair.

Dr. F. PARKES WEBER read a paper on Acute Ménière's Symptoms in Spleno medullary Leucocythæmia, with special reference to the Anatomical Changes found in Acute Leucocythæmic Affections of the Ear (a pathological report on the internal ears being supplied by Mr. Richard Lake). The patient was a man, aged 31 years, suffering from advanced leucocythæmia (this term being used as synonymous with leukæmia). He was admitted on March 31st, 1898, to the German Hospital with great enlargement of the spleen and liver. He had had malaria six years previously. He died on Oct. 1st, 1898, from collapse following internal hæmorrhage. During life the ophthalmoscope showed the presence of the so-called "leukæmic retinitis." About six months before his death he was attacked with acute ear symptoms (headache, vertigo, and vomiting). Examination of the patient's hearing, &c., pointed to the symptoms being probably due to a leucocythæmic affection of the internal ears; and in a very short time the man became quite deaf. Post-mortem examination of the ears proved that a portion of the scala tympani (one side only examined) and the perilymphatic spaces of the semicircular canals (both sides examined) were filled up with newly formed fibroid and bony tissue. The scala vestibuli, canalis cochleæ, and vestibule showed only comparatively slight changes. Transverse sections of the nerve trunks showed no obvious change. A short account was given of similar cases which had been published. From a comparison of the various cases it was concluded that the pathological appearances presented by the internal ears after death differed in different cases, partly in accordance with the length of time which had elapsed between the onset of the acute aural symptoms and the death of the patient. In most cases of acute leucocythæmic affection of the internal ears post mortem investigation suggested that the following was the sequence of events: the commencement of the aural symptoms (vertigo, headache, vomiting, and deafness) marked the occurrence of more or less extensive extravasations of blood in the semicircular canals and the cochlea, the process being doubtless nearly always more or less symmetrical and simultaneous in the two ears. In such cases, though apparently lymphocytic infiltration and hæmorrhages might be found in various parts of the ears after death, the labyrinthine hæmorrhage was probably the essential lesion which gave rise to the acute aural phenomena in question. Subsequently vascularisation and organisation proceeded in the usual manner, with the result that the clot became gradually replaced by newly formed connective tissue, closely connected by its blood-vessels with the endosteum of the bony labyrinth. In process of time (if the patient lived long enough) more or less ossification occurred in the newly formed tissue, and irregular processes of bone projected inwards from the walls of the bony labyrinth. At this stage of the pathological process transverse sections of the bony semicircular canals mostly showed the membranous canals surrounded by a meshwork, or by irregular masses of newly-formed bone and fibroid tissue, completely filling up the perilymphatic spaces. Besides the striking cases in which acute (apoplectiform) Ménière's symptoms occurred there were also leucocythæmic patients, as pointed out by Schwabach, who presented aural troubles of a less severe or less sudden nature. These lesser symptoms might be in part altogether independent of the leucocythæmia, but in part due to small hæmorrhages and patches of lymphocytic (leucocythæmic) infiltration in various part of the auditory apparatus. Dr. Weber drew attention to the light thrown by leucocythæmic cases of Ménière's symptom-complex on cases associated with constitutional disorders other than leucocythæmia (such as arterio sclerosis, syphilis, chronic gout, renal fibrosis, and the various cachectic conditions in which hæmorrhages often occur). He sketched a rough pathological and clinical classification of such cases; the exact nature, however, of the pathological condition in the ear could not often be determined with certainty merely from the symptoms observed during life.

Dr. F. W. MOTT narrated particulars of a case resembling that of Dr. Weber's in some respects, though differing in others. The patient was a man, aged 38 years, who was admitted into Charing-cross Hospital on Nov. 10th, 1899. He was said to have had a severe attack of "influenza" two years before, since which date he had been in bad health. Six months before admission he was seized with sudden pain in the left side of the abdomen, and a little later with pain in the head and deafness, with loss of power of maintaining his equilibrium. The deafness came on suddenly, first in the left and then in the right ear. On admission he looked dull and was a little cyanosed, the temperature being 97° F. He gave his answers very slowly. The abdomen was distended, and the liver and spleen were very large. The lymphatic glands were also enlarged. The blood contained only 54 per cent. of hæmoglobin, but the main change was an enormous increase in leucocytes, of which there were almost as many as red corpuscles. There were large numbers of multipartite nucleated white cells, very few lymphocytes, and a good many myelocytes (with big nuclei). The muscular power of the patient was good; there was no loss of coordination in the arms, but he could not balance himself in walking and could not stand at all with his eyes shut. He was at first thought to have hæmorrhage into the cerebellum. The knee-jerks were absent on both sides. Vision was very imperfect. Accommodation was good, but the right reflex was sluggish. The fundi showed slight changes. The hearing improved considerably. Taste and smell were normal. He responded to questions in a drowsy manner. Seven days after admission he was found to be stone deaf in both ears on waking in the morning. Three days later he died comatose. At the necropsy the liver weighed five and a half kilogrammes and the spleen 1·8 kilogrammes. The blood was of a dirty brick-red colour; there were hæmorrhages into the brain which was congested. Both the petrous bones were soft and friable from rarefaction of the bone. The spinal cord and nerves showed no degeneration. There was hæmorrhage into the posterior spinal roots and hæmorrhage into the cochlea. The hæmorrhage into the semicircular canals accounted for the loss of equilibrium. This and the deafness were accounted for by hæmorrhage into the cochlea and labyrinth. Dr. Mott's paper was illustrated by lantern slides.

Mr. RICHARD LAKE, in replying, remarked that the ligamentum spirale had not previously been described as being ossified, but this lesion existed in Dr. Weber's case. It was the perilymphatic spaces in the semicircular canal which had been nearly filled up with newly-formed fibroid and bony tissue (microscopic specimens were exhibited). In Dr. Mott's case there was wanting any new formation of bone; but the hæmorrhage had produced the same symptoms. He would like to ask what the porosity of the bone was to be attributed to.

Dr. MOTT, in replying, said that his case resembled myelogenic leukæmia. The proliferation of the bone cells was probably in some way connected with the fragility of the bones.

Dr WEBER remarked that in Dr. Mott's interesting case the three distinct attacks differed from most cases. The fact that the organ of Corti was preserved accounted for the recovery of hearing. The penis was an organ liable to be early attacked in leukæmia and priapism was sometimes the first symptom of the disease to attract attention.

MEDICAL SOCIETY OF LONDON.

Adjourned Discussion on the Pathology and Treatment of Appendicitis.

A MEETING of this society was held on Feb. 26th, Dr. F. T. ROBERTS, the President, being in the chair.

The discussion on the Pathology and Treatment of Appendicitis was resumed, the PRESIDENT remarking that speakers were invited to discuss the subject under four headings: (1) the non operative treatment; (2) the indications for operation; (3) the nature of the operation advised; and (4) the after-treatment of the case.

Mr. MARMADUKE SHEILD congratulated Mr Lockwood on his success in explaining or associating pathological conditions with clinical manifestations. His contributions on the subject constituted a distinct step forward. Bacteriological invasion of the coats of the appendix was at the bottom of most of the symptoms. First, as to non-operative treatment it would never be found that all would agree. In his opinion this expectant plan of treatment was only justifiable in very mild cases. In general terms the more severe the case the more urgent the necessity for operation. Great pain and vomiting and quickness of pulse were certainly indications for operation. In mild cases he would watch and do very little, avoid opium (except in very small doses), and give mild aperients. The great difficulty in such cases was to tell what was going on in the appendix. For example, he remembered a patient, aged 16 years, attacked for the first time with slight pain in the iliac fossa, and very mild symptoms, though the pulse was over 120. The symptoms did not call far immediate operation. However, an exploratory operation was done and in removing the appendix it burst and a lot of pus poured out. Secondly, turning to the indications for operation, most would agree that fulminating and recurrent cases should be operated on without hesitation. But in slight cases there would be much difference of opinion. It was a common error to suppose that if no lump could be felt cases could wait and *vice versâ*. The fact was that if a lump could be felt cases could wait with less danger than if no mass could be felt. In the latter condition, if the symptoms, and especially the pulse (which should be taken every hour), indicated progression, these were the very cases on which operation—at any rate, an exploratory operation—should be performed. In the third place, as to the details of the operation, he thought, as a rule, that the incision should be as small a one as possible, and his plan was to split the muscles, not to cut them across. But in cases of difficulty the opening should be as large as necessary for manipulation and exploration. Stitch-abscesses in the abdominal wall might be avoided by the use of kangaroo tendon. Silk should not be used in muscles and the stitches need not be drawn too tight. Finally, as regards the after-treatment, powerful salines by the mouth and turpentine enemata were the only hints he could offer. No two men could ever quite agree as to the procedure and he thought that physician and surgeon should consult in most cases. The higher the rank of the patient in life the less chance he would seem to have of recovery from appendicitis, and he had witnessed several tragedies among the better class of patients from the desire on the part of the patient, and even his medical advisers, to avoid the risks of an operation which, after all, were *nil*.

Dr. H. A. Caley wished in the first place to reply to the criticism that cases of appendicitis which in a recent paper he had classed as "recovered" could not be regarded as "cured" because they might subsequently relapse. He pointed out that care had been taken to exclude all cases—some 30 per cent. of the total—in which recurrence subsequently occurred from the 99 of his illustrative series of 200 cases referred to as having recovered from the attack. A small proportion of these cases might have had relapses and have been treated elsewhere, but any such source of error could not detract from the general conclusion that a larger proportion of cases of the milder forms of appendicitis did recover from the attack and did not experience recurrence. This was of much importance in relation to treatment. It involved the inference that there was a large class of cases in which operative treatment could not be regarded as necessary. The all-important consideration in relation to treatment in the first instance was whether operative measures were or were not called for. He regarded as unequivocal indications for operation conditions which corresponded with any one of the three following groups: (1) appendicitis with diffuse peritonitis, actual or threatened, including the acute fulminating cases of perforative or gangrenous appendicitis; (2) appendicitis with local suppuration; and (3) relapsing and chronic cases. Practically, however, if the case were seen early it might be quite impossible to determine to which category it belonged, though the prospect of recovery turned upon anticipating a generalised peritonitis. He therefore considered that to the above three groups, in which on definite pathological grounds operation was advocated, there should be added a fourth group of borderland cases—(4) acute cases of appendicitis other than those associated with diffuse peritonitis, in which the suddenness of the onset, the severity of the initial symptoms, and the clinical conditions as a whole pointed to a severe lesion. Under such circumstances an exploratory operation was preferable to the delay involved by waiting for the further development of symptoms. In this connexion a frequent, and more especially an increasing, pulse-rate was highly significant. If the above four groups were treated by operation a large proportion of all cases still remained for non-operative treatment. In reference to the administration of opium Dr. Caley considered that judiciously employed it was of great value. Two important provisos should be borne in mind: first, opium or morphine should, if possible, not be given, certainly not continuously, until the case had been carefully investigated with a view to deciding as to the question of immediate operation; and secondly, it should not be given as a routine measure, but only to meet certain definite indications, such as pain, and should be discontinued as soon as the particular indications had been met.

Mr. Harrison Cripps agreed with Mr. Sheild's eulogy of Mr. Lockwood's paper. Cases of appendicitis fell naturally into two categories: (1) comparatively mild attacks of intermittent inflammation; and (2) severe cases. In the first if the patient had one attack only, and that a mild one, he would not advise interference; but if he had a second or third then it showed that there was some abiding cause and operation was indicated. The risk to life was much less from operation than from letting the patient alone. He, like others, had had no fatal cases. Some surgeons had operated on 130 cases consecutively without one fatal issue. As to the symptoms, the absence of swelling and local tenderness were not indications that nothing was going on. The swelling and tenderness depended on the position of the appendix and the thickness of the abdominal walls. Mr. Cripps mentioned a case in which he had found a swelling in Douglas's pouch which was thought to be an inflamed ovary. It was operated on and found to be quite nine inches away from the usual position of the appendix which constituted the swelling. As regards the fulminating cases, he was not so sure what was the best course to advise. The risk of operation was considerable, but the risk of leaving them alone was greater. He thought that operation should be done at once in such cases except in those instances where it was evident that an abscess was forming but not yet completely formed; then a day or two's waiting was perhaps advisable. As to the details of the operation he thought the incision should be of good size. He did not approve of a pad being worn afterwards; it increased the tendency to prolapse and was not necessary if the patient kept quite quiet after operation.

Dr. William Hunter said it must not be lost sight of that 70 per cent. of the cases recovered without the surgeon ever seeing them, a fact which surgeons were too apt to forget. It was customary to make three pathological types of the disease—the catarrhal, the ulcerative (with concretions), and the fulminating (necrosis of the appendix). But the important point was that no distinction could be drawn between these as regards infectivity. A so-called catarrhal appendicitis infected the whole thickness of the wall of the bowel, as might be seen from some of the specimens which he had exhibited. As regards the indications for operation he thought that if the temperature rose after the first attack a surgeon should be called in. He believed that some advocated waiting until pus formed, but he did not agree with this. All cases were undoubtedly bacterial and infective, and the whole question was one between the amount, on the one hand, of resistance of the appendix and the constitution on the other. It was not possible to lay down absolute rules for decision, but it was best to regard all cases as potentially suppurative. It was generally considered imperative to clear out the lower bowel, but how could this influence the pathological process of the lesion? Was it not more important to keep the patient as quiet as possible? And, again, to this end small doses of opium, short of causing narcosis, with calomel, or some other intestinal disinfectant, were valuable remedies.

Mr. Macadam Eccles considered the successful surgical treatment of acute appendicitis depended chiefly on two conditions. The first was the virulence of the bacteria and the second the rapidity with which the diagnosis of the certainty of inflammation could be arrived at. The facility with which they invaded not only the walls of the structure but also the tissues of the meso-appendix had been clearly proved by Mr. Lockwood's sections. Mr. Eccles was at the present time investigating the bacteriology of what would be termed the normal appendicitis and had been greatly struck with some facts which he hoped to bring forward on a future occa- The diagnosis within the first 36 hours was not easy and vas ample time for the bacteria to migrate far beyond men of the appendix. Supposing the case was left un- ed the natural course would be either for the inflamma- to diminish, possibly to disappear, or suppuration to or in comparatively few instances perforation and al peritonitis. If the inflammation subsides the ndix could be subsequently removed with less than tesimal risk. If an abscess formed this could be dealt , as statistics abundantly proved, with comparative y. He therefore considered that unless it was possible al with the case within a few hours of the onset it was rally wiser and the result likely to be more successful he operator waited a few days; but each case must be n on its own merits.

r. MANSELL MOULLIN quite agreed with the last speaker in every case they had to do with infection. Turning to he cases in which suppuration occurred he thought they e much commoner than was usually believed, and where symptoms suddenly subsided he thought it might possibly explained by sudden bursting of the pus into the intestinal al. What medical measures, he asked, were there, which re really capable of controlling the diseased process? ile, on the other hand, the operation was a perfectly e one. If at the end of 24 hours the pulse was still going and the symptoms were progressing, and if they were still ng so at the end of 36 hours, he thought that an exploratory eration was the only justifiable course. When there was usion into the right iliac fossa the case would in any case obably relapse, and he did not altogether agree with Dr. lchin. He thought in general terms that physicians and neral practitioners did not call the surgeon in to see the ses early enough.

Mr. LYNN THOMAS (Cardiff) had operated on 41 cases, which two had died. Much profit might be derived, he ought, from cases of mistaken diagnosis. For instance, ne case was sent in as a case of typhoid fever. Another ase of appendicitis turned out to be gonorrhœal salpingitis. third case with typical symptoms turned out to be abscess f the right ovary with pyosalpinx. A fourth case turned out to be duodenal ulcer, and in a fifth case occurring in a hysterical young lady the appendix was found to be absolutely healthy, and the patient was cured by Weir-Mitchell treatment. In the last 13 cases he had operated on he closed the wound with silk and with buried sutures, and he preferred this method because he believed it prevented hernia.

Mr. JAMES BERRY, referring in the first place to chronic relapsing cases, remarked that the operation was never fatal if done in the quiet intervals. As regards the operation itself the incision should be free and through the sheath of the rectus. He preferred silk and buried sutures. He had never had an after hernia with this method. The peritoneum should be sponged, not washed. He had had an excellent opportunity of comparing different methods of treating the peritoneum, and this point came out very clearly. He did not think cases of first attack should be operated on too early. It was a curious circumstance that if ever a surgeon suffered from appendicitis he almost invariably sent for a physician, but perhaps they were only affected with the milder cases which tended to spontaneous recovery.

The PRESIDENT remarked on the difficulties which might arise in connexion with the social position of the patient. He thought the best way to deal with these cases was by consultation between the physician, surgeon, and family practitioner.

Dr. W. H. ALLCHIN wished to urge the fact that there was a very large proportion of cases which needed no operation. No doubt all the cases were really infective in character. He felt that they were much indebted to Mr. Lockwood for his valuable contributions in this direction. The chief contra-indication to operation was undoubtedly the slow or moderate pulse, especially if the other features were not progressive. Any localised swelling was certainly of itself not a definite indication for operation. The administration of opium enabled the surgeon to make much better and truer observations on the pulse by relieving the restlessness and pain.

Mr. C. B. LOCKWOOD, in reply, was not surprised at the line the discussion had taken. But as regards the making of rules it was clearly impossible when even diagnosis was uncertain. He remembered one case which was variously diagnosed gall-stones, appendicitis, and (by himself) as some renal affection. Again, how could rules be formulated when the nature of the lesion was so uncertain and variable from day to day? A case of ulceration of the appendicitis one day might be gangrenous the next and perforative the next. The question what constituted a rapid pulse was a reasonable one, though anything over 100 indicated danger. Many speakers had spoken casually of appendicular abscess, but it was a most difficult thing to diagnose. But here, again, why not ascertain for certain by means of exploratory operation? He would like to know what was meant by a mild lesion and what were the symptoms which corresponded with it. Was it ulceration? As regards so-called cures he still thought this treatment should not be used. A patient left the hospital, it was true, but if he were watched and followed up a recurrence was always possible. The appendix might even appear quite normal to the naked eye and yet be diseased, and for his own part he would always choose a surgeon who would remove the appendix and not leave it behind.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Feb. 23rd, Dr. LEONARD SEDGWICK, the Vice-President, being in the chair.

Dr. STCLAIR THOMSON exhibited a case of Primary Tuberculosis of the Nasal Septum. The patient was a young woman who had already been shown before the society in October, 1897. In July, 1896, a growth of the size of a filbert was removed from the right side of the septum, diagnosed as tuberculous, though no bacilli were present. Three months later the base of the growth broke through the septum. She had active local treatment and three injections of Koch's tuberculin, to which she reacted. There were several other reasons in support of the diagnosis. When recently examined it was seen that the perforation had increased in size, but the condition in other respects was better. Sections showed giant cells and caseation but no bacilli. The treatment was painting with Mandl's solution of iodine and iodide of potassium and, later, guaiacol and olive oil. The progress had not been very satisfactory and Dr. Thomson said that he would be glad of suggestions for treatment.—Mr. ARTHUR BARKER referred to a case of very extensive tuberculosis of the nose which had involved the lacrymal sac and had perforated the soft palate. Treatment by painting with the perchloride of iron and copious dusting with iodoform had proved very successful.—Dr. PERCY KIDD agreed that the lesion was probably tuberculous, although the microscopical appearances were not conclusive. The sputum did not pass this way and that was probably why tuberculosis was so rare in this position.—Dr. THOMSON, in reply, remarked that there was no part of the respiratory tract so rarely attacked. He had been unable to find a record of any other observation of primary nasal tuberculosis by a British observer. Even as a secondary affection it was rare, although the larynx was so frequent a seat.

Mr. JACKSON CLARKE showed a female infant, aged one year and five months, with well-marked Lateral Curvature, probably due to rickets. The deformity was first observed at the age of 13 months. Such cases required, in addition to general treatment (diet, cod-liver oil, &c.) and daily manipulations, the use of an effective instrument. If left to themselves the patients became too often severely deformed and from the alteration of form of the thorax they suffered from respiratory and circulatory embarrassment, the cardiac and respiration rhythm being frequently doubled when adult life was reached. The form of support that was, in his experience, the most serviceable was the simpler form of Chance's splint. Poroplastic and other corsets and recumbency caused loss of muscular strength and general depression of physiological activity, and they were on this account to be avoided.

Mr. W. H. BATTLE exhibited a case of Operation for Traumatic Dislocation of the Knee. The patient was a woman aged 50 years. She was admitted for an injury to the right knee sustained during an attempt to enter a train while in motion. There were considerable bruising and displacement of the knee, and upon examination of the joint three of the ligaments (internal lateral and both crucial) were found to be ruptured. It was examined with the x rays and this revealed extensive injuries to the joint surfaces. No improvement having followed manipulation it was decided to open the joint. On August 5th a free incision was made across the front of the joint. On opening the joint the anterior crucial ligament was seen to be torn away from the femur and the posterior crucial ligament lacerated. These were sutured and the internal lateral ligament was repaired. The case did well except for a little suppuration on the inner side of the wound and the patient could now walk normally. The patient had for all practical purposes recovered the use of the joint.

Mr. T. H. KELLOCK showed a case of Achondroplasia in a boy, aged four and a half years, the second of a family of four, the other children being normal. He was born easily at term, but had a "queer shape" even then. He was breast-fed until ten months; he began to crawl at six months, but did not walk until two years old. He was only 30½ inches in height (39½ inches being the normal), the deficiency bearing on the lower limbs, the bones whereof were shorter than usual and the epiphyses abnormally large. The head had a large vault and a narrow base and the patient presented the usual lordosis, prominent abdomen, genu retrorsum, waddling gait, and spreading fingers, all features characteristic of such cases, in addition to the peculiar manner of raising himself. The child was intelligent and had had good general health.

Dr. CHARLES W. CHAPMAN showed a father and son presenting a Peculiar Congenital Deformity of the Hands, with, in the child, Absence of the Radius. The right hand of the father exhibited the peculiarity in respect of the three phalanges that the second was flexed at a right angle on the first and the third on the second. The thenar eminence was almost entirely absent and abduction and adduction were non-existent. In the left hand the terminal portion, representing the thumb, was united for two-thirds of its extent with the index finger, and there was a wide cleft between the first and second fingers. The man used the index finger like a thumb and the hand served for most purposes. The son, an intelligent boy, aged three years, exhibited the following deformities. On the right, the thumb at its terminal part resembled a finger. It had three phalanges, the second and third being permanently flexed on the first. On the left there was an entire absence of the radius with a club hand of the radio-palmar variety.

Dr. LEONARD GUTHRIE showed a case of Asthenic Bulbar Paralysis (Strümpell's) occurring in a female, aged 23 years. She had been a waitress accustomed to long hours. Two years ago she noticed difficulty of articulation occurring only when she was tired. In July, 1899, deglutition and mastication became affected and she was unable to close her eyes fully. There was no history of sore throat. At the present time she showed paresis of the orbicularis oculi and oris, of the tongue, pharynx, and soft palate, but of no other muscles. The eyelids could not be completely closed and there was no resistance to passive elevation of the upper lids. There was no ptosis or paralysis of the ocular muscles, intrinsic or extrinsic. The optic discs were normal. The mouth was flabby and the labial fissure was widened. She could not whistle or blow out a candle and had difficulty in emptying a spoon with her lips. Food collected in the right side of her cheek and she had some loss of control over the movements of the tongue during the first act of deglutition. The tongue could not be curled transversely, thus demonstrating the association between the action of the lingual muscle and the orbicularis oris. The movement of the soft palate was deficient. Fluids regurgitated through the nose and she choked in trying to swallow solids. The voice was nasal and the explosive labials B P and gutturals were indistinctly sounded. The vocal cords acted normally. All the symptoms varied from day to day in degree and were much more pronounced after fatigue or using the voice. She could swallow and speak well in the early morning after a night's rest. The only other symptom was occasional weakness of the fingers of the right hand which prevented her from sewing. The case was held to belong to the class called by Strümpell "asthenic bulbar paralysis." Patients suffering from similar symptoms were apt to die suddenly from respiratory failure, but hitherto no pathological changes had been found after death, thus supporting the view that a toxic influence was at work in the bulbar centres rather than a degeneration of the nuclei or the peripheral nerves. The patient had improved considerably under treatment by rest and the administration of strychnia.

Dr. C. E. BEEVOR showed a case of Paralysis of the Seventh, Eighth, Ninth, Tenth, and Eleventh Cranial Nerves in a woman, aged 32 years, who six years ago contracted syphilis. The present symptoms had come on during the last two and a half years, most of them within six months. The symptoms now present consisted of right optic neuritis (partial), absolute deafness of the left ear, taste lost in the left side of the tongue front and back, complete left facial paralysis, including the platysma, paralysis of the soft palate (left side), difficulty in swallowing, some anæsthesia on the posterior wall of the pharynx, paralysis of the left vocal cord, wasting of the left side of the tongue, with fibrillar tremors and protrusion to the left, the left sterno-mastoid completely and the left trapezius partially paralysed. None of the paralysed muscles reacted to faradaism. The most probable diagnosis was syphilitic meningitis affecting the nerves of the medulla.

Dr. J. S. COLLIER (for Dr. HUGHLINGS JACKSON) showed a case of Unilateral Lesion of the Pons. The patient was a man, aged 40 years, with no pathological history, whose illness began gradually with giddiness, deafness of the left ear, alteration of speech, difficulty in guiding the left arm, diplopia, difficulty of swallowing and mastication, and loss of feeling on the left side of the face. There had been no headache, vomiting, or dysuria. The optic discs were pale and there was paralysis of the fifth, sixth, seventh, and eighth cranial nerves on the left side, with weakness of the ninth, tenth, and eleventh. He held his head in the right cerebellar position. There was a spastic condition of the right arm and leg, and the speech resembled that often met with in cases of disseminated sclerosis. Dr. Jackson had met with cases of that disease which had begun in that way.

Mr. A. E. BARKER showed a girl who first came to him 13 years ago with Macroglossia, when he removed a wedge-shaped portion of the organ, bringing the sides together. The case is recorded in vol. xli. of the Transactions of the Pathological Society. She had returned last year with recurrence, the growth this time being in the direction of the hard palate, and on this occasion he had removed a wedge-shaped piece in a horizontal plane, bringing the upper and lower flaps together. Sections of the first growth showed a preponderance of lympho-angiomatous tissue, but the recurrent growth was more of a nævoid character.

Mr. F. C. WALLIS showed the following cases:—1. A case of Tuberculous Disease of the Knee-joint in a child, aged three years, which was treated by division of the patella, free exposure of the joint, removal of the affected synovial membrane with scissors and spoon, and finally swabbing the whole surface with pure carbolic. The patella was united by silk-worm gut and the skin wound was closed except for a gauze drain which was removed after 24 hours. The child was now able to walk about and had a limited movement of the joint which was improving. Mr. Wallis mentioned another case of erasion and one of excision of the knee-joint, both treated with carbolic, and they had done well. 2. A case of Acute Infective Osteomyelitis in a child, aged 12 years, with necrosis of the whole of the shaft of the humerus. The large sequestrum was removed (this was shown with the patient). The periosteum was much thickened all round the sequestrum, forming a good scaffolding. The arm, which before the operation was useless, was rapidly regaining power, especially since massage had been begun. 3. A case of Osteitis and Periosteitis in a child, aged 11 years, which had been treated by cutting down on the tibia, elevating the periosteum, and cutting a deep groove through both the epiphysis and the diaphyses. Since the operation the pain had disappeared and the child could stand. The case was originally thought to be tuberculous.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Eclampsia.—Basilysis.—The Use of Levurine.

A MEETING of this society was held on Feb. 14th, Dr. J. W. BALLANTYNE, the Vice-President, being in the chair.

Professor A. R. SIMPSON showed: (1) A Hydatid Mole; (2) a bottle of Levurine; (3) the Head of a Child delivered by Basilysis; and (4) two Uteri Removed by Pan-hysterectomy for Fibroids.

Dr. J. W. BALLANTYNE showed: (1) A Fœtus with Absence of the Radii and Deformity of the Thumbs, which was the third monstrosity with the mother out of six or seven pregnancies; (2) a Fœtus with Anencephaly; and (3) Photographs of Historical Teratological Phenomena.

Dr. KEPPIE PATERSON showed a Myxomatous Mole.

Dr. MACVIE read a paper on a case of Eclampsia having a Peculiar Puerperal History, with Observations on Coma. The patient was a woman of neurotic disposition and anticipated her labour with helpless timidity and dread. Her first labour was easy with a slow recovery. Her second labour was easy and she did well till the end of the first week when a gradual stupor set in, which deepened and became profound in the next few days. The pulse was slow and soft, the breathing was quiet and shallow with intermittent sighs, and the temperature was normal. The bowels acted fairly well with drugs. The urine was scanty and deposited urates, but was otherwise normal. The treatment was mainly nutritive and designed to keep the heart going. When death seemed imminent consciousness gradually returned and in a week the patient was well except for debility. She regained her strength but slowly. Her third labour was favourable, but on the seventh day she became listless and apathetic, her look became vacant, and stupor gradually intervened, though not so profound as in the previous puerperium. At her fourth confinement she was found to have œdema of the ankles and the urine on boiling deposited about one-half albumin. The presentation was by the face. The membranes were ruptured and the child was easily delivered by forceps under chloroform. Six hours afterwards a fit occurred, followed rapidly by eight or nine others, and in two hours she had become unconscious with stertorous and laboured breathing. Venesection was performed and about nine ounces of blood were withdrawn. Improvement in the breathing and colour of the patient was almost immediate and deglutition power returned. Hot water was given freely. Consciousness soon returned and steady progress occurred during the next few days. The urine then only contained a trace of albumin. She continued well for three or four days when apathy began, which gradually deepened into a profound stupor. From this she never rallied and death occurred on the tenth day of the puerperium. In discussing the case and the treatment of eclampsia Dr. Macvie advocated chloroform in the stage of convulsions to narcotise the brain centres and to allay peripheral irritation. He believed that the state of coma was mostly induced by the venous congestion of the brain during the tonic spasm of the chest in the convulsion. This stage was therefore best met by inhalation of oxygen and venesection. Elimination of the poison causing the fit was helped mainly by the administration of warm fluids, either by the mouth, subcutaneously, or by the rectum.—Professor SIMPSON, Dr. F. W. N. HAULTAIN, and Dr. FREELAND BARBOUR made remarks on the paper.

Professor A. R SIMPSON read a paper on Basilysis. He said that improvements in the construction of the forceps and a better appreciation of the conditions under which turning, Cæsarean section, and symphysiotomy could be safely carried out had in recent years greatly restricted the group of cases in which the obstetrician felt called upon to deliver by cephalic embryotomy. There was still, however, a not inconsiderable field for the employment of embryotomy procedures, as might be gathered from the papers written on the subject. The basilyst was used first for perforating the cranial vault and it was then bored into the cranial base and broke it up. The chief drawback to the cranioclast was that in some cases it did not fracture enough of the base of the skull to allow of the perfectly easy extraction of the head. The point of the basilyst was conical, with a double-threaded screw thread on it. This was applied to the vault and by twisting the handle it was easily screwed through the bone; by pressing the blades of the handle a segment of the point was opened out and the perforation was enlarged in all directions. After washing out the brain the screw-point was applied to the base of the cranium, the sella turcica, or ethmoid, and these bones were broken up. The head then collapsed very readily. A fenestrated blade for application outside the skull could be locked on to the basilyst and extraction was thus made easier in difficult cases. The whole instrument had been recently improved and made much lighter. An illustrative case was given and the head was shown.—Dr. BALLANTYNE, Dr. BARBOUR, Dr. HAIG FERGUSON, Dr. FORDYCE, and Dr. HAULTAIN made remarks on the paper.

Professor SIMPSON read some Notes on the Use of Levurine. Levurine was a dried extract of beer yeast (*levures de bière*) which was prepared by Dr. Aragon and M. Couturieux of Paris. They were stimulated to the preparation of this drug by a paper on the use of barm in diabetes mellitus. Levurine had also been found to be of value in furunculosis. It was therefore not a new drug, but was the yeast of beer so prepared that it was concentrated in powder form. It was always fresh, constant in its action, and was prepared in an easily administrable form. It might be taken in beer or in aerated water, or in cachet form. The dose was a tea-spoonful three times daily until the desired effect—viz., arrest of suppuration or reduction of temperature—was attained. Dr. Aragon and M. Couturieux suggest that its effect was produced by counteracting a latent glycæmia or by acting as a germicide to streptococci and staphylococci or as an antagonist to their toxins. Professor Simpson reported a case of appendicitis where each time the temperature rose to 100° F. a dose of levurine brought it down to about normal. It also gave good results in a case of tuberculous ulceration and the drug was administered to a septic puerperal patient with evident advantage. It had also been stated to have been beneficial in furunculosis, tonsillitis, and pneumonia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

Protamines and their Cleavage Products.—Model of Viscera.—Mucous Glands.—Epiphyses of Human Bones.—Form and Position of the Stomach.—Viscera of the Gibbon.

A MEETING of this section was held on Feb. 2nd, Professor W. H. THOMPSON, the President, being in the chair.

The PRESIDENT read a paper on Protamines and their Cleavage Products. Protamines, hitherto obtained only from the ripe milt of various species of fishes, are believed by Kossel to be the simplest proteids. On hydrolytic cleavage they yield mainly hexone bases—viz., arginine, with histidin and lysine in some cases. These bases have recently been shown to exist largely in antipeptone. It appeared desirable, therefore, that their physiological properties, as well as those of the protamines, should be examined. The experiments were performed on anæsthetised dogs in the Physiological Institute, Marburg, and yielded the following results. The protamines were found to be very poisonous, the maximum non-lethal dose being one-fifth of a gramme. Their effects in many ways resembled those of the albumoses; blood-pressure was rapidly and profoundly lowered, but with a moderate dose returned to normal in half an hour. Coagulation was greatly retarded and the number of leucocytes in circulation were largely reduced. These effects were also temporary. Respiration was peculiarly influenced; the movements were at first greatly accelerated and exaggerated; then came a gradual decline, ending in complete cessation. After a few seconds diaphragmatic respiration returned and gradually became deeper and deeper, the movements of the thoracic walls during this period being wholly passive. Subsequently (after the lapse of an hour or more) active thoracic respiratory movements reappeared and the function gradually became normal. Other muscles—viz., those of the trunk and limbs—were also temporarily paralysed. None of the cleavage products showed these effects, nor did a trace of residue, which splits off in addition to the hexone bases, during the process of hydrolysis. Histon, a substance obtained from lymphoid organs, which had considerable chemical resemblance to the protamines, produced almost identical physiological effects. Antipeptone had very little effect on blood-pressure and blood coagulation. It raised blood-pressure slightly and hastened coagulation. Arginine hastened blood coagulation, while its effect upon blood-pressure was practically *nil*—i.e., its effects coincided with those of antipeptone. These substances reduced enormously the number of leucocytes in the circulation, but the leucocytes reappeared in about three-quarters of an hour; they could not, therefore, have been destroyed nor have wandered out of the blood vessels.—Professor COFFEY, Dr. WALTER SMITH, and Dr. DAWSON discussed the paper.

Dr. C. J. PATTEN, in the unavoidable absence of Professor Cunningham, exhibited for him a model of the Thoracic and Abdominal Viscera from behind which had been prepared primarily to exhibit the form and relations of the spleen.

Professor COFFEY showed sections which illustrated the Formation and Manner of Development of the small Racemose Glands of Mucous Membranes. The specimens were taken from the œsophagus of snakes. The earlier stage was seen in the simple alveolus or sac opening without a duct on the surface.

Dr. KNOTT exhibited a large series of Human Bones, all of which presented non-united or partially united Epiphyses. The series illustrated the development of the limb bones, the pelvis, scapula, sternum, clavicle, metacarpals, metatarsals, phalanges, vertebræ, ribs, and a large number of cranial bones. Amongst the specially interesting items were an atlas which was obtained in process of ossification from at least nine centres and an ulna which presented a small epiphysis on top of the ordinary epiphysis for the upper end of the olecranon process, a centre of ossification which, up to this, seems to have completely escaped the notice of anatomists. When the elbow-joint was bent this supernumerary epiphysis presented a striking resemblance to a diminutive patella turned upside down.—Professor BIRMINGHAM said that many of Dr. Knott's series were of the greatest interest, particularly those of the atlas and ulna. He was not satisfied, however, that the additional centre for the olecranon was constant.

Professor BIRMINGHAM gave a lantern demonstration of the Form, Position, and Relations of the Stomach as seen in bodies which have been hardened by intravascular injections of formalin. The chief points upon which he dwelt were that the empty stomach was contracted, not collapsed, its pyloric portion resembling thick-walled small intestine; its cardiac portion was rounded but attenuated; its surfaces looking, the one up, the other down, and its long axis nearly horizontal. In this condition it rested on the "stomach bed," occupying only the lower part of the "stomach chamber," the upper part of this space being occupied by the great omentum and the transverse colon, which doubled up over the empty stomach and lay between it and the diaphragm. The large, flattened, and collapsed stomach, with anterior and posterior walls in contact, usually described and pictured, was not found in the hardened body. Three stages were recognised in passing from the empty to the distended condition. In the first the fundus and cardiac portions were expanded, the pyloric portion remained contracted, and the lesser curve sharply bent as in the empty state; in this stage the stomach resembled a Florence flask, strongly bent at the junction of the neck and the body. In the second stage the cardiac portion was further expanded, and the pyloric portion opened out, but the junction between the two was distinctly marked. In the third stage there was an enlargement of all the axes of the organ; the distinction between pyloric and cardiac parts was almost lost; the pylorus was carried an inch or two to the left of the middle line and the antrum pylori was developed. But in all these changes there was no rotation around the long axis of the organ, with a raising up of the great curvature, &c., as commonly described. The distended stomach lay obliquely, its long axis running from the fundus, not vertically, as had been taught in recent times, but inwards and downwards, making an angle of from 40° to 45° with both the horizontal and mesial planes. In a female subject with a very constricted waist the stomach lay almost vertically on the left side of the vertebral column. Régarding the question of the existence of a valve at the cardiac orifice, he thought that little reliance could be placed on observations made on dried specimens. The return of food from the stomach into the œsophagus would be amply guarded against by the contraction of the muscular fibres of the œsophagus and the crura of the diaphragm, as illustrated by a specimen exhibited.—Dr. PATTEN and Mr. TAYLOR discussed the paper.

Dr. PATTEN brought forward a communication dealing with the form and position of the Thoracic and Abdominal Organs of the Gibbon. The lungs, heart, stomach, and spleen very closely resembled those of the human subject, as one might anticipate in such a highly developed anthropomorphous ape. The specimen was first hardened in formalin to ensure the contour of the viscera.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this institution was held on Feb. 22nd, Mr. W. T. Thomas, the Vice-President, being in the chair.—Mr. R. W. Murray showed a patient upon whom he had performed the operation of Tarsectomy for Double Club Foot.—Dr. W. Alexander related two cases in which he had removed Foreign Bodies from Viscera and showed specimens of these bodies—(1) pieces of coal and pebbles removed from the vagina; and (2) a piece of slate pencil removed from the male urethra.—Mr. Rushton Parker read a paper on Recent Operations on the Stomach, comprising 15 cases, of which eight occurred in the last six months and 12 in the year. Four of the operations were gastrostomies in men for carcinoma of the œsophagus, the operation being that known by the names of Hahn, Frank, and Albert. Two of the patients died within six months from acute phthisis, one in six days from bronchitis, and one in three months suddenly from syncope. He considered the procedure in suitably selected cases of value, but probably it was the least satisfactory of the temporary operations on the stomach. Four were gastro-enterostomies, three in men and one in a woman. The symptoms in all of the cases pointed to carcinoma, and although a tumour was felt only in two cases, in all a growth was found which was either too firmly fixed or surrounded by secondary deposit to permit of removal. Two of the patients were still doing well; the others were getting worse; in one the tumour was increasing and there was undoubtedly cancer, whilst in the others no microscopical verification had been made, and between carcinoma and gumma there was no means of being certain in the examination by eye and hand alone. The operations were well borne and the healing was rapid. No adventitious appliances were used. The nearest piece of jejunum was attached to the lower part of the stomach, an incision three inches in length being made in the axis of each viscus, and continuous silk sutures being used, one set through the mucous membrane and another through the peritoneum. The operation quickly admitted of satisfactory feeding, and although it was only required for temporary purposes it might now and then give permanent relief in the event of suspected carcinoma proving to be non-malignant. Two cases of excision were shown, one being that of a woman, aged 37 years, for malignant disease (ascertained microscopically) to the left of the pylorus who was still in good health and without any sign of recurrence after two years, and the other that of a man, aged 49 years, upon whom pylorectomy was performed a year previously for a tumour, which was thought to be malignant, but which at the operation was regarded as gummatous and which proved microscopically to be so. Three cases of pyloroplasty were discussed, two for contracted pylorus due to gastric ulcer and the other for ulceration (probably syphilitic) contracting the right half of the stomach. Two patients were shown after perforation of gastric ulcer. One was a chronic perforation with limiting adhesions to the liver necessitating complete section of the stomach near the cardiac end before suturing and the other was a perforation operated upon within six hours of the accident; hour-glass contraction of the stomach existed to the diameter of an inch, with the perforation in front of it. Free incision of the contraction right and left was made, the edges of the perforation were cut away, and the wound in the stomach was drawn together end to end and separated in the middle as in pyloroplasty. Both of the patients were in good health.—Mr. F. T. Paul agreed that Frank's modification of Hahn's operation of gastrostomy was the best, but unless a diverticulum of from two inches to two and a half inches in length could be withdrawn to form the fistulous passage in the abdominal wall it was better to do Senn's operation, which he thought the more efficient but not so easily recovered from as Frank's. He had ceased to use all mechanical appliances except Murphy's button, and this he believed might generally be dispensed with. In gastro-enterostomy he considered there was a danger of the intestinal juices escaping into the stomach and of the anastomosis proving only temporary; the former trouble was more common in the posterior operation and was rarely met with when the opening was made in front. This operation could not compare with either pylorectomy or pyloroplasty in the benefit afforded to the patient. Pylorectomy was never likely to be a frequent method of operation in cancer of the pylorus, owing to the fact that by the time the diagnosis was made the extent of the growth, fixation, &c., might render it unfeasable. Pyloroplasty had given him the best results in practice. With reference to the suture of perforated gastric ulcer he considered that drying out the peritoneal cavity was better than flushing. He always washed viscera that were withdrawn from the abdomen, but he limited the internal flushing to localised septic tracts that were isolated by adhesions or otherwise.—Mr. Robert Jones referred to a patient with a

Large Nodular Mass at the Pylorus which was so fixed that after opening the abdomen pylorectomy was considered undesirable; now, three years later, the patient was nearly well and the tumour had disappeared. This was of interest in view of reported cases of gastro-enterostomy for malignant disease when years had passed and the patient lived. A microscopic examination was necessary before malignancy could be pronounced.—Mr. W. Thelwall Thomas drew attention to the unsatisfactory state of our knowledge as regarded the pathology of the stomach, two of the cases referred to in the paper being due to syphilis—a cause rarely mentioned.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Feb. 16th, Dr. Franklin Parsons, the President, being in the chair.—Dr. Hope, medical officer of health of Liverpool, read a paper on the Housing of the Working Classes in Liverpool, illustrated by a large number of coloured plans, sections, and elevations. The problem of the housing of these classes, including the skilled artizans, the unskilled labourers, and the "submerged tenth," was one, he said, which at the present time the sanitary authorities of every large town in Europe and America had to face. It was rendered the more difficult by the facts that a large proportion of these men, as dock labourers, market porters, and others, must live near their work and that the greater part of the houses occupied by them were erected before any building regulations came into existence, massed together without open spaces or sanitary conveniences and falling into decay. The area covered by these might be, and often had been, cleared, but the substitution of sanitary dwellings fulfilling present-day requirements, with open spaces, baths, and wash-houses, &c., at rentals such as the classes in question could afford was no easy matter. It was worse than useless to attempt to provide decent accommodation for the idle, drunken, and criminal class; their dispersal was best for themselves and for the community: but few places could show such satisfactory results from the improvement of the dwellings of the poor as could Liverpool, to which city was due the honour of having been the first to initiate legislation in this direction. During the last 15 years nearly 4500 "court houses" had been demolished, their sites having been covered by buildings such as he was about to describe; but there still remained over 3000, more than three-fourths of which were in the courts, the rest facing the streets, but back to back with the former. The width of the courts was on an average eight feet and of the approaches from the street from two to three feet; each court contained from eight to ten houses, of three rooms one above the other, each reached by stairs or ladder from the one below, all back to back and side to side, without any sanitary conveniences whatever; water-closets, used in common, were placed at one end of the court and dust bins at the other, the water-supply being from a hydrant in the middle. It was in such areas that fevers were endemic, that epidemics of cholera and typhus fever did havoc, and that notwithstanding the palliative efforts of the authorities, scavenging twice daily, unlimited water-supply, prompt removal of the sick, and practicable prevention of over-crowding, the (crude) death-rate ranged from 40 to 60, even reaching at times 75, per 1000. These three-roomed houses being so numerous, and their insanitary character not recognised, no attempts were made until recently to put up cottages with fewer than from four to five or six rooms except that from time to time since 1863 three- and four-storeyed blocks had been erected by private enterprise; but while each tenement was beyond the needs and means of the very poor the owners were of opinion that the rentals of from 1*s.* 3*d.* to 1*s.* 6*d.* per room did not give a return for the capital invested. Those erected by the corporation dated from 1868, when six large blocks, from three to five storeys in height, each containing four-, three-, and two-roomed tenements, were put up and let at about 1*s.* 5*d* per room, and included Victoria-square, opened in 1885; Juvenal-dwellings, opened in 1895; and Arley-street and Gildart's gardens, opened in 1897. They were controlled by a resident superintendent and an assistant, who also collected the rents, the management of the entire property being vested in sub-committees of the corporation. Dr. Hope gave full details of the numbers of tenements with one, two, and three or four rooms respectively, the rental of each, and the dimensions of the several rooms, as well as the returns of original cost and annual income and expenditure on each estate, which might be summed up by the statement that 90 three-roomed, 300 two-roomed, and 70 single roomed tenements, at rents from 2*s.* to 3*s.* for the last, from 3*s.* to 5*s.* for the two-roomed, and from 4*s.* 6*d.* to 5*s.* 6*d.* for the largest, gave a net profit of from 2½ to 4½ per cent. on the outlay. Another property was in course of development to comprise 132 and ultimately 182 tenements, mostly two-roomed, but in some respects an improvement on those already described, for while they were provided with water-closets on the landings, one to each two or three families, every one of the new tenements would have its own, and hot water would be laid on to the sinks for which 6*d.* per week would be added to the rent, gas would be supplied through automatic meters, and provision made for storage of fuel and of food in a locker ventilated from the outer air. There would be a large recreation and reading room for the tenants.—Mr. Shirley Murphy, referring to Dr. Hope's statement that the death-rate in the new buildings did not exceed 21 or 22, remarked that the death-rate was determined far more by the habits of the occupants than by the sanitary conditions of the house. Water-closets within the dwelling, though harmless in themselves, might be dangerous nuisances if dirty and neglected or out of repair.—Dr. E. F. Willoughby deprecated the position of the water-closets in some of Dr. Hope's plans in the interior of a small tenement, and he also objected to any arrangement that necessitated crossing a backyard at all hours and in all weathers. He strongly recommended an arrangement adopted in some blocks of placing the closets in pairs, one above the other, from the ground floor to the topmost storey, one on each side of an addition built out in the rear.—Dr. Bulstrode, Dr. Newsholme, and the President also took part in the discussion.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held at the City Orthopædic Hospital, London, on Feb. 17th.—Mr. G. Chisholm Williams showed cases of (1) Ganglion of the Extensor Tendons of the Foot; (2) cases of Caries of Dorsal Vertebræ; and (3) Severe Hallux Valgus with Hammer-toes.—Mr. Muirhead Little showed a boy, aged 10 years, with Stiff Shoulder probably due to Tuberculosis. There was a history of injury. When first seen nine months ago the humerus was firmly fixed on the scapula; its head was slightly displaced upwards and inwards. There was no swelling or sign of local inflammation. Under an anæsthetic the humerus could be easily moved on the scapula through about 90° of abduction. Rotation was very limited. There was a roughness in the movement of the joint. The other shoulder-joint allowed an unusual degree of mobility, so that the boy could turn his olecranon to the front. Both elbow-joints were normal except for slight hyper-extension.—Mr. John Poland showed a skiagram of a case of Hallux Varus, probably of paralytic origin. He had replaced the bones after dividing the tendon of the abductor pollicis and internal lateral ligament.—Mr. Jackson Clarke read a paper introducing a discussion on Hallux Valgus and Varus and Analogous Deformities, which is published at p. 609 of our present issue.—Mr. John Poland referred to the skiagram he had previously shown of a case of hallux varus. He now showed a skiagram of a remarkable congenital case. The condition was not alluded to in books. There was great developmental abnormality and the second phalanx was completely displaced to the inner side of the first. As suggested by Mr. Tubby, it was very probably a congenital dislocation analogous to congenital dislocation of the hip. As regarded hallux valgus there was a class of cases of great interest of which nothing or little had been said in the text-books. These cases were those of children from 14 to 15 years of age who had not worn tight or narrow-toed boots. He had operated on many such.—Dr. Robert Jones said that he preferred to treat the subject from a clinical rather than a pathological standpoint. He thought that the extensor of the great toe played a large part in producing and maintaining hallux valgus. He was in the habit of dividing or of excising an inch of the tendon. The best treatment in pronounced cases was excision of the head of the first metatarsal bone, but many patients would not consent to operation. These could be successfully treated by gradual mechanical correction if they chose to undergo the pain and trouble. There was no need to apply any apparatus in the day time. In excising the head of the metatarsal bone it was most important to remove enough bone. He had seen a boy, aged 14 years, with well-marked hallux valgus, yet this boy had never worn boots or shoes; he sold newspapers in the streets of

Liverpool. Mr. Jones had found that osteotomy of the shaft of the metatarsal bone was useless.—Mr. Tubby agreed with Mr. Jackson Clarke as to the osteo-arthritic nature of the deformity, but he would say that not merely 50 but 90 per cent. of the cases were due to rheumatoid arthritis, which he believed was a dyscrasia, apt to fall upon any joint which happened to be exposed to pressure or irritation. If enough bone was removed there was no need to divide the extensor proprius pollicis.—Mr. Muirhead Little referred to the dislocation of the sesamoid bones which occurred in hallux valgus. These showed plainly in skiagrams on the first inter-osseous space and had been removed by at least one surgeon as the probable cause of symptoms. There must be thousands of cases of hallux valgus which produced no symptoms unless arthritis supervened or was the original cause. Toe-posts were useless. He suggested that the cases in young people described by Mr. Poland were analogous to hammer-toe and were due to defective growth of the external lateral ligament as compared to the bones.—Mr. Keetley said that he thought that one broad line of treatment by excision of the head of the metatarsal bone was the best. He had found that wedge osteotomy was sometimes effective. He had never succeeded in curing any case by any mechanical appliance, though he had given many cases a very fair trial. He thought that there were two classes of cases—those associated with flat foot and (the great majority) those caused by improper boots. He did not believe—apart from rickets—that hallux valgus affected people who had never worn boots.—Dr. Blagg said that there were three classes of cases, namely—(1) congenital; (2) due to rheumatoid arthritis; and (3) due to tight boots. When he was a student he had seen operations of osteotomy and the immediate results seemed excellent, but when he got into practice he found that the trouble recurred after osteotomy and excision of the head of the bone had to be performed.—Mr. Noble Smith said that in the slighter cases much might be done by persuading the patients to wear proper boots.

Clinical Society of Manchester.—A meeting of this society was held on Feb. 20th, Dr. Judson S. Bury, the President, being in the chair.—The President showed a case of Idiopathic Muscular Atrophy and a case of Unilateral Paralysis of the Serratus Magnus.—Dr. A. Wahltuch showed two patients:—1. A girl, aged 10 years, suffering for 12 months from Hemichorea of the Right Side, who developed during the early stages of the illness an inequality in the pupils of the eyes, the left being enlarged and slower in contraction than the right. The vision in both eyes was perfect, though there was a slight astigmatism in the right. She attended as an out-patient at the Hulme Dispensary and was treated twice a week by massage and was now considerably improved, the twitchings being very rare and slight. 2. A girl, aged three years, suffering from Congenital Infantile Paralysis in the right leg and forearm; the supinators and extensors of the forearm and the peroneus longus were chiefly affected. She was brought to the Hulme Dispensary in August, 1899, the mother stating that the child had never been able to walk. Treatment by massage and electricity improved so far that she could now walk, run, and extend the fingers, though supination was still difficult.—Dr. W. Milligan mentioned the case of a patient who suffered from chronic Suppurative Middle-ear Disease complicated with extradural abscess and lateral sinus thrombosis and upon whom he had operated with a successful result. The patient, who had suffered for many years from suppurative middle-ear disease, suddenly developed acute symptoms—viz., pain in the head, high temperature, rigors, nausea, &c. Three weeks after the onset of the symptoms and when the patient was suffering from profound septic poisoning operation was performed. A large extradural abscess was opened and drained; the lateral sinus which was found ulcerated through and thrombosed at the distal end was freely scraped and packed with gauze. A second deep-seated cervical abscess round the jugular vein was also opened and drained, the vein itself being tied and divided. Localised pneumonia developed after the operation, probably due to a pulmonary infarct. The patient, however, finally made a good recovery.—Dr. Milligan also showed a patient upon whom the Stacke operation had been performed for Chronic Mastoid Disease with satisfactory results and made some remarks upon the rationale of the operation and the methods by which the most rapid healing could be secured.—Dr. W. E. Fothergill and Dr. J. W. Stenhouse described the case of a woman, aged 32 years, who, before completing the seventh month of her first pregnancy, developed Excessive Swelling of the Legs and Body which extended up to the lower ribs. The urine turned solid on boiling and contained a quantity of bile. About one-third of a pint was passed per diem. The liver was tender and was at first increased in size. In spite of active treatment the patient became worse, fluid collected in the abdomen, and the liver dulness became reduced to two and a half inches. The stools were absolutely without chyle. Labour was induced as a last resort and she rapidly improved thereafter. In less than a month her urine was copious and contained a normal amount of urea, whilst there was no bile in it, and only 0·1 per cent. of albumin. The liver had resumed its normal size, the action of the bowels was correct, and every trace of œdema had disappeared. The case was brought forward as an example of one of the forms in which hepatic toxæmia occurred during pregnancy. Poisons probably derived from the alimentary canal, and which should be destroyed by the liver, were, through failure of the functions of that organ, allowed to remain in the circulation. The kidneys also failed to excrete the poison which produced extreme renal irritation. Other manifestations of auto-intoxication during pregnancy were mentioned briefly.—Mr. J. E. Platt showed a patient, a blacksmith, aged 41 years, upon whom he had operated for aneurysmal varix of the brachial artery and median basilic vein and partial division of the median nerve. 14 months previously the man had received a small, punctured wound immediately below the bend of the elbow. Two weeks later he had been subjected to operation, and a piece of steel, three-quarters of an inch in length, had been found embedded in the brachial artery near its bifurcation. The median nerve had been found to be divided for the inner three-fourths of its extent. The brachial, radial, and ulnar arteries and the median basilic vein had been ligatured and the nerve sutured. Recovery of the function of the muscles supplied by the median nerve had subsequently progressed slowly but surely and was almost complete at the time the patient was exhibited. Some remarks were made upon the treatment of aneurysmal varix and upon the period necessary for recovery after division of motor nerves.

Windsor and District Medical Society.—A meeting of this society was held at the Guildhall, Windsor, on Feb. 21st, the President, Mr. W. B. Holderness, J.P., occupying the chair.—Mr. Noble Smith gave a demonstration of some Interesting Surgical Cases (upwards of 13 in number) illustrated by Casts, Radiographs, Models, and Photographs. The first case was one of Pott's fracture. Nine months after the accident the patient was hardly able to get about. A radiograph showed the foot to be so much displaced outwards that the weight of the body was transmitted through the centre of the tibia and impinged upon the inner edge of the astragalus, thus pushing the foot towards a valgus position. The fibula, which had been fractured diagonally and had united with much thickening, was chiselled through and the tendo-Achillis was divided, whereupon the foot could be immediately placed in a better position. The aching pain previously felt was at once relieved and at the end of six weeks the patient was able to walk about far more comfortably than before the operation. The second and fourth cases were examples of supposed bow-leg. Mr. Noble Smith, however, employed radiography which clearly showed fractures of the tibia one and a half inches above the ankle-joint. These were cut down upon and the bone was straightened, the patients making good recoveries. The fifth case was one of dislocation of cervical vertebræ. A lady sustained a fall of 80 feet down some rocks in the island of Sark. After some weeks' rest she began to get about again and then suffered from pain and stiffness in her neck. Attacks of giddiness likewise occurred and so affected her that she would suddenly fall down and especially on placing her hands upon her head in attempting to dress her hair. On examination Mr. Noble Smith detected an angular deformity between the fifth and sixth cervical spines and a radiograph clearly indicated a partial displacement between these vertebræ. The patient was placed under ether and firm extension made upon the head. Some adhesions were first felt to give way and after more force had been applied a slight gliding movement was felt in the neck. It was then found that the vertebra occupied their natural position. The acute symptoms shortly disappeared and the patient was now practically quite well. Mr. Noble Smith quoted also the case of a woman who, whilst sleeping with her arm thrown over the back of a chair, suddenly started up and "ricked" her neck. A similar luxation had taken place. A fortnight later he lifted up the head to a considerable degree and suddenly imparting a lateral gliding movement a distinct "click" was heard and the patient was instantly relieved. Among other cases described were four of knock-knee, three of coxa vara, and one of marked deformity in the lower limbs, probably due to fracture in early childhood. Referring to the subject of club-foot Mr. Noble Smith said that he and his colleagues at the City Orthopædic Hospital were unanimously opposed to severe osteotomies except in cases accompanied by great bony deformity. They strongly disapproved of Phelps's operation in which all the soft parts were cut through down to the bone, the resulting gap, sometimes two inches in width, being stuffed with gauze. A disastrous example of this procedure was mentioned in which necrosis of bone and other troubles occurred, and this was contrasted with a severe case of club-foot (casts shown) treated with gradual pressure by small iron splints and division of contracted tendons. It was of the first importance to overcome the inversion before dividing the *tendo-Achillis*. For spinal curvature Chance's splint had the great merit of stimulating the development of the back muscles (photographs shown). He deprecated Calot's operation, which had been attended with no small mortality and of which he had seen some lamentable examples.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on Feb. 7th at the Medical Institute, Birmingham, Dr. Rickards, the President, being in the chair.—Mr. Gilbert Barling showed a Kidney removed for Calculous Pyonephritis by lumbar nephrectomy from a woman, aged 49 years. The patient had had symptoms for about 12 months, during which time she had suffered from severe attacks of pain in the right side, from frequency of micturition, and from a swelling which had gradually increased in size. At the time of operation the kidney formed a tumour reaching mesially to within an inch of the umbilicus, backwards into the loin, downwards into the iliac fossa, and upwards under the ribs. The kidney was separated from its surroundings with great difficulty, the peritoneum being widely torn during the process of separation, and at the lower end of the organ a piece was torn out at the junction of the internal, external, and common iliac veins. The hæmorrhage from the torn veins was small and easily controlled by ligature of the three veins. A good recovery followed with practically no œdema of the right lower extremity. Examination of the kidney showed an abscess cavity holding about four ounces of pus and other tiny points of suppuration in the organ. A calculus was fixed in the pelvis and there was a good deal of atrophy of the renal substance. Though some renal tubules and glomeruli still existed the bulk of the kidney tissue was replaced by fat. There was some interstitial and parenchymatous nephritis, but casts were not found before the operation, the explanation possibly being that the ureter was blocked The excretion of urea before the operation was about 300 grains and this had remained pretty constant since the operation.—Dr. Douglas Stanley showed a boy suffering from Favus and remarked on the rarity of the disease in the Midlands.—Mr. Chavasse showed a Sacculated Aneursym removed from a man, aged 41 years, who had suffered from syphilis; it was of the size of a large orange and was situated in the upper part of the abdominal aorta. The only symptoms present during life were attacks of pain resembling those of renal colic and limited to the left side. Rupture of the sac had taken place posteriorly and extravasation into the substance of the left psoas muscle caused a large sub-peritoneal hæmatoma. Erosion of the bodies of the last two dorsal and upper two lumbar vertebræ existed. A slight pouch was also found at the extreme convexity of the arch of the thoracic aorta.—Mr. Haslam showed a Tumour of the size of a walnut that he had successfully removed from the left ulnar nerve in the middle of the arm of a patient, aged 38 years. The tumour had been growing for eight years and consisted centrally of blood-clot and around this a layer of angiomatous tissue.—Mr. Chavasse showed a Large Hydronephrotic Cyst which he had successfully removed by abdominal nephrectomy from a boy, aged 11 years It was apparently congenital (the abdomen having distended from birth) and contained five pints 12 ounces of clear straw-coloured fluid, which chemical analysis showed to contain urea, uric acid, and traces of albumin.—Dr. Murray read a paper on Chronic Brass Poisoning.

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—At a meeting of this society held on Feb. 22nd at the Public Hall, Canning Town, Dr. J. Biernacki gave an address on Diphtheria. After a reference to the modes of infection a clinical description of a typical fatal case was given with a chart in which were shown the falling temperature, the progressing diminution of urine, and the blood-pressure curve. It was stated, as the result of numerous investigations with the Hill-Barnard pocket sphygmometer, that a fall in pressure invariably accompanied the disease, slight at the outset, but becoming extreme in fatal cases. The initial drop was attributed to relaxation of the blood-vessels from the direct action of the toxin, an effect anticipated from the recent experimental work of Dr. T. G. Brodie; while heart failure was added as a more potent factor in the final depression. This speaker expressed the conviction that all the symptoms of the disease were to be referred to the diminution in blood-pressure—pallor with coldness of the surface, sickness, compressibility, and final disappearance of the pulse, a reduced temperature, restlessness (jactitation), and especially oliguria, going on to suppression, which locked up, not only the toxin, but also the physiological poisons.—A discussion followed in which Mr. A. E. Kennedy, Mr. Percy Rose, Mr. Stewart Boyd, Dr. Beaumont, and others took part.

Reviews and Notices of Books.

The Principles of Treatment and their Applications in Practical Medicine. By J. MITCHELL BRUCE, M.A. Aberd., M.D., F.R.C.P. Lond., Physician and Lecturer on the Principles and Practice of Medicine, Charing cross Hospital; Consulting Physician to the Hospital for Consumption, Brompton; Examiner in Medicine, University of Cambridge. Edinburgh and London: Young J. Pentland. 1899. Pp. 614. Price 16*s*.

WE have rarely perused a book with more satisfaction than we have Dr. Mitchell Bruce's work on "The Principles of Treatment." A treatise of this nature was wanted and practitioners and students will find a study of it most valuable. The usual manner in which therapeutics are taught is unsatisfactory; in the majority of cases treatment appears to be purely symptomatic or empirical. Long dissertations are given by the bedside on the etiology, pathology, and symptoms of a disease, whilst the treatment is usually dismissed in a few words. There are, fortunately, teachers exceptional in this respect, but we believe we are correct in the general terms in which we have spoken. Dr. Bruce alludes to this defect in his preface and comments on the immense difficulties which students experience when they are called upon to show an intelligent acquaintance with treatment. They may write a prescription with little hesitation, but as a rule they cannot give a rational account of the principles on which they have planned it, apparently being ignorant of the principles which control successful and rational therapeutics. The work is planned on excellent lines. It starts by assuming no therapeutical laws, but proceeds to find them in the familiar facts of etiology, pathological anatomy, and the clinical characters of disease. These are carefully examined for the elementary principles of treatment, and in the course of the inquiry the reader is taught how he may himself employ his observations as guides to practice. This is the only way in which a truly correct line of treatment can be mapped out and one which will abolish routine and frequently harmful methods of the use of drugs.

Dr. Bruce remarks in his preface that the principles of treatment are difficult to discuss, and still more difficult or impossible to appreciate, without illustrations of them in connexion with [illegible] d[illegible]. Throughout the first part of the work [illegible] ..d and to statements of principles are made without reference to some familiar instances in which they apply, but in the second part of the work a large number of illustrations are given, exemplifying the principles enunciated in the first part.

The principles of treatment founded on etiology are first discussed, and a distinction is made between efficient causes on the one hand and predisposing and determining circumstances on the other. Micro-organisms, animal parasites, poisons, unsuitable food, traumata, mechanical strain, cold and heat, all receive due attention, "indications for treatment" based upon the various etiological factors being considered at length.

"Principles of Treatment Founded on Pathology" naturally form an important part of this work. It is refreshing to read the paragraphs relating to inflammation, ulceration, necrosis, degeneration, hypertrophy, and atrophy, these subjects being considered from a therapeutical point of view. We are shown how the result of these processes as a whole may be either successful or otherwise. Success means regeneration and recuperation, and the final result of these is recovery, complete or incomplete. In too many instances, however, the different processes of spontaneous recovery entirely fail. Instantly, suddenly, or slowly, as the case may be, the pathogenetic influence and its effects overwhelm or otherwise overcome the various provisions for recovery with which the body is furnished. The result is death—swift, rapid, or slow; but unless the pathogenetic agent be instantaneous or crushing the body makes an effort or attempt at reaction or recovery. It is further argued that whilst natural resistance continues and can be advantageously aided and controlled the prominent feature of pathology from the therapeutist's point of view is recovery in the form of both anatomical and physiological repair and associated processes. These may be effected by structures and vital functions over which we have abundant control. Our opportunities of rational interference are thus proved and the treatment of pathological processes is fully justified.

The chapters on "Principles of Treatment Founded on the Clinical Characters of Disease" are equally interesting. It is quite rightly insisted that the appreciation of the importance of the indication for so-called expectant treatment in acute diseases (particularly such as are of limited duration) constitutes a turning-point in the history of medicine, and scarcely less valuable are the indications for the prevention and treatment of complications and sequelæ and for the thorough establishment of convalescence which an improved knowledge of these parts of the natural history of disease has enabled us to reach.

The first part of the book terminates with chapters on "Principles of Treatment Founded on the Personal Factor in Disease," "The Proper Relation of Treatment to Disease," "Means of Treatment," and "The Art of Treatment." The second portion of the book will be found most useful for reference. It is headed "Illustrations of the Principles of Treatment" and, as its title indicates, it shows the method of applying the principles laid down in the first part to the treatment of diseases. Separate chapters are devoted to different diseases or groups of diseases and the information imparted will be found most valuable by practitioners who desire to ascertain the lines of treatment which they should adopt in any particular case.

We can strongly recommend the book to our readers and we offer our congratulations to the author on the excellent work which he has produced.

Text book on Palæontology. By KARL VON ZITTEL. Translated by C. R. EASTMAN, Ph.D, Harvard College. London: Macmillan and Co. 1900. Pp. viii. & 706. Price 25*s.* net.

THIS is a translation of Dr. Zittel's smaller work upon palæontology and will be completed with the issue of Vol. II. The present volume, of large dimensions and most copiously illustrated, deals with the invertebrates only; the concluding volume will have for its subject the more important group of vertebrates. More important, that is to say, from the point of view of palæontology; for with abundant and often well-preserved bones to handle it is possible to come to reasonable conclusions about the relations of extinct creatures to their living allies. With invertebrates, on the other hand, there is, save in rare cases, little left but their shells or spines and other hard bits which, though useful enough, are often precisely those regions of the creature with which we could best dispense. The study of invertebrate palæontology is productive of annoyance for this very reason. Some delightfully "aberrant" mollusc or worm has left only miserable evidence of itself in the shape of a damaged shell or even a mere cast—just its imprint upon the muddy flat where death overtook it or the waves left it. The palæontologist wonders, and unfortunately is compelled to continue wondering, whether some of those remarkably persistent types of life, such as the brachiopod lingula, concealed under an identical exterior an interior diverse from their descendants of to-day, or whether they are permeated through and through by a conservatism which has hardly a parallel in the animal world. Unlike ourselves, the author of the volume before us commences logically by defining what a fossil is before proceeding to speak of fossils and their occurrence. The common idea is probably of some animal or plant turned to stone. Dr. Zittel naturally does not sanction so loose and inaccurate a notion as this; he would, and very properly, define fossils as "all remains or traces of plants and animals which have lived before the beginning of the present geological period and have become preserved in the rocks." This broad definition will include the frozen carcasses of mammoths exhumed in Siberia, whose flesh formed an admirable though rather expensive diet for the dogs who assisted in the disinterment, no less than the most stony of Dura Den red sandstone fishes. The line, however, is a little hard to draw with accuracy and decision. We rather gather that the author would not allow the skull of the Canstadt man to be a fossil, since he denies this distinction to the peat-entombed remains of the dodo. This does not appear to be quite logical. The dodo is, for all practical purposes, as effete as the trilobite, though it was undoubtedly, in quite recent times, seen alive by many, including John Evelyn. This, however, is a small criticism. The reader who is imperfectly acquainted with the subject will, on turning over the pages of this book, be struck with the fact that so many groups of animals are excessively abundant, while others are as rare, in the rocks and clays of the world. The author finds himself obliged to devote 260 pages to the consideration of the shellfish (mollusca), while he *only needs* 60 for the crustacea. The enormously hard and stony carapaces of many crabs would seem to lend themselves to preservation just as well as, if not indeed better than, the comparatively thin shells of many bivalve molluscs. The group of isopod crustaceans, including among living forms the familiar wood-louse, is dismissed in a little under one page; and yet this is not negligence or ignorance on the part of the author: in that exceedingly short space he has said what is to be said (on the lines adopted through the book) about that at present very large and widely-spread race of creatures. There must be some reasons, with which we do not seem to be acquainted at present, for the paucity of one race as fossils and the abundance of others. It is not, of course, surprising to find that fossil butterflies and moths occupy only half a page. These tender insects must crumble away directly after death; and, indeed, everyone knows that a dead butterfly is as rare as that proverbially rare creature a dead donkey. Generally speaking, the remains of terrestrial animals are scarcer in the rocks than those of aquatic animals.

And among aquatic animals those which formerly inhabited the sea are decidedly more abundant than fluviatile or lake-dwelling animals. This, of course, is natural and readily explicable. A land animal dying upon the land has but little chance of leaving its remains behind it in a state fit for interpretation by a palæontologist, whereas the marine crustacean or mollusc sinks into soft mud in many cases, and is rapidly entombed and preserved until future upheaval for the advantage of the student.

In considering the past history of fossil vertebrates and their relations to existing forms much has been done in tabulating the modifications of structure through which they have passed before arriving at that form which characterises them at present. Pedigrees of, in some cases, highly probable accuracy have been made out concerning the descent of such types as the horse and the camel. With invertebrates the general results are disappointing. The common sea urchins of our own coasts recede into the "infinite azure" of a most dim and palæozoic past. Yet these early urchins, different though they are in many particulars from their living representatives, have already got the same stony plates arranged with the same almost crystalline regularity. It is true that the ancient forms have more rows of plates on their "tests" than those which we can dredge off our coasts; but the veriest tyro would not hesitate for one second in assigning them to the same group. There is no hint afforded by the study of palæontology—of a kind that can be argued out with success—of any closer approximation of the primitive types to other allied forms of echinodermata, such as starfishes or sea cucumbers. An echinus has been always definitely an echinus. There is here at least no limbo to which vague forms of intermediate characters can be profitably relegated.

The fact of the matter probably is that we do not and cannot go far back enough into time to obtain a glimpse of those early creatures which were the ancestors of what are now quite separate groups The imperfection of the geological record about which so much has been said is no doubt also an imperfection of another kind than that usually meant when the phrase is used. That there are many hiatuses to be deeply deplored is true enough; but what is to be most regretted is that the beginning seems to be irrevocably lost. The gaps may be filled, for there are the rocks, and hammers are plentiful, but there is no known method of re-stratifying a crystalline and altered rock. In the echinoderms, which we have just been considering, but much more in the shellfish, the lack of plasticity in the outward form is remarkably noteworthy. The abundant figures which illustrate that section, as they do all the other sections, of the volume will show the very close likeness which the most ancient forms of molluscs bear to those actually living. The bivalve shell of the earliest times is often—save, of course, to the expert—a mere replica of that of forms which strew the beach at any seaside place. The innumerable æons through which the same type of defensive armature has been preserved is astounding. Their consideration affords a strong argument against a progressive evolution without the stimulation of natural selection. The shell once acquired proved, we may suppose, to be the best and least expensive form of protection during a life by no means so complicated as that of a terrestrial animal, and was therefore preserved without much alteration. On the other hand, it may, of course, be argued that the small changes, comparatively speaking, which have occurred cannot be due to anything like competition, since it is hard to understand how a slight alteration of engraved lines upon the shell could affect the well-being of its inhabitant.

Professor Zittel's book is not a book to be read through at once from cover to cover. It is really a work of reference and as that is very full. Though an abridgement of his more extensive work (which we should much like to see translated) it is quite full enough in those places where we have tested it. The translator has not acted only in that capacity. Dr. Eastman has, with the sanction of the author, "remodelled, enlarged," and generally brought up to date the whole work. In this he has been assisted by many eminent experts, chiefly in the United States. There is no doubt that he and his colleagues have performed a useful piece of work in producing this sufficiently full account of the zoology of extinct invertebrates.

LIBRARY TABLE.

Health Abroad: A Medical Handbook of Travel. Edited by EDMUND HOBHOUSE, M.D. Oxon. London: Smith, Elder, and Co. 1899.—We believe that this will be found to be an extremely useful book, not only to the ordinary traveller, for whom apparently it is intended, but also to the medical practitioner who may wish to supplement his often somewhat meagre knowledge of "foreign parts." The contents consist of a bibliography of very great interest and value, the works enumerated being numerous and well selected. There is a general introduction by the editor, very short and, of course, general, but still conveying many useful hints. Dr. Leigh Canney contributes the article on North Africa, which includes Egypt, Tunis, and Algiers. The article on Egypt is first, and due prominence is given to its peculiarly dry and fine winter climate, with guidance, prudent on the whole, as to the various places and their peculiarities. As to the route Dr. Canney has fallen into error in saying or implying that the P. and O. boats from Marseilles run to Alexandria. Every traveller must wish that they did. The article on South Africa is by Dr. Guillemard and that on Central Africa by Dr. Battersby. The former has, of course, a peculiar and painful interest at present. The editor writes on North America and the West Indies, Dr. Pennell on South America, the editor again on Australasia and on the Riviera, while Dr. Tidey contributes the article on Switzerland and Italy, and Dr. Simpson that on India The articles all bear the impress of knowledge derived at first hand, and they have therefore a high degree of practical usefulness. We congratulate the editor on the idea of publishing a book of this kind and on the very successful manner in which he has accomplished the work.

Professions for Boys and How to Enter Them. By M. L. PECHELL and JAMES J NOLAN. With a preface by the Most Reverend J. E C. WELLDON, D.D. Second edition. London: Beeton and Co, Limited; Simpkin, Marshall, Hamilton, Kent and Co, Limited. Pp. 316. Price 3*s.* 6*d.*—The word "profession" is used somewhat loosely in this book, for the callings mentioned embrace nearly every known one, from the Navy, which begins the list, to the Church Missionary Society, which closes it. Curiously enough, two eminently pleasant callings are not considered—namely, the Diplomatic Service—although there is an article on Student Interpreters—and the various clerical posts to be gained in the Houses of Parliament True, such posts are only for the few, but they are worth the winning. In the chapter upon Medicine and Dentistry there are some statements which are not quite clear. Thus, "the university degree implies an arts education; the diploma does not." An "arts education" may mean anything. All the examining bodies require candidates for degrees or diplomas in medicine to have passed certain examinations in arts, but the University of Oxford stands alone, we fancy, in demanding that candidates entering for her examinations in medicine should previously have taken a *degree* in arts. Trinity College, Dublin, however, will not confer a medical degree without an arts [illegible] but the arts course and the [illegible] for each [illegible] article will be found useful to those desirous of entering what is possibly the most arduous profession of any, but one which, at the same time, has its prizes both in interesting work and in emoluments.

Jahresbericht uber die Fortschritte auf dem Gebiete der Chirurgie. (*A Year-book of Progress in Surgery.*) Redigirt und herausgegeben von Professor Dr. HILDEBRAND in Berlin. III. Jahrgang, bericht über das Jahr 1897. Wiesbaden: Verlag von J. F. Bergmann. 1898. 8vo, pp. 1102. Price 25*s.*—This useful book, which may be obtained in Great Britain from Mr. Bauermeister of Glasgow, is the third issue. It contains *résumés* of all, or nearly all, articles on surgery which appeared throughout the world in the year 1897. When we noticed the previous volume we praised its conception and arrangement, and equal commendation is deserved by the present book. Some such work as this is well-nigh indispensable for a writer on any department of surgery who wishes to be aware of what has been written already on the subject. Two suggestions we should like to make. The first is that more differences in the type employed would render conspicuous names and subjects which have at present to be sought for carefully in a mass of text. The other suggestion is that a little more care should be exercised in revising the spelling of the personal names which occur. We are well aware of the difficulty there is in ensuring the accuracy of names, especially of foreign names, but a little revision will do much. Hardly any praise is too great for the general arrangement of the volume.

The Mechanics of Surgery, comprising Detailed Descriptions, Illustrations, and Lists of the Instruments, Appliances, and Furniture necessary in Modern Surgical Art. By CHARLES TRUAX. Chicago. 1899. Pp. 1024. Price $4.50.—This is an account of modern surgical instruments by one who is a member of a firm manufacturing instruments, but it is in no way a price list and the personal element is kept as much as possible in the background. There are so many instruments nowadays and so many patterns and forms of the same instrument that most medical men feel rather at sea when they wish to purchase some new appliance. This book is intended to assist them in their choice, and so far as we have seen they will not go far wrong if they follow the advice which this volume contains. There are, it is true, many small points on which our opinion does not quite coincide with the author's, but we have not discovered any instance in which the difference is of any real importance. The book contains, also, an account of trusses, of splints, and of artificial limbs. In his remarks on the fitting of artificial limbs to stumps the author does not attempt, like so many makers of these appliances, to dictate to the surgeon where he should amputate, but he explains the conditions which render one form of stump more convenient than another for the patient. The book should prove of real service to anyone who wishes to purchase an instrument with which he is not personally acquainted.

Cancer, Illustrated by 1000 Cases from the Registers of the Middlesex Hospital and by 50 Selected Cases of Cancer of the Breast, &c. By THOMAS WILLIAM NUNN, F.R.C.S.Eng., consulting surgeon to the Middlesex Hospital. London: H. J. Glaisher. 1899. Pp. 89 Price 2*s.* net.—This little book consists of two parts; in the first is given an account of the structure and life-history of carcinoma, in the second part are contained the notes of 53 cases of this form of tumour affecting the breast. When the connotation of a popular term is exactly equivalent to the connotation of its scientific representative there can be no objection to employing it even in scientific treatises; but when the popular term and the scientific are distinctly not equivalent the one to the other only confusion can arise from employing the popular expression. The word "cancer" amongst the public is employed to mean any growth which tends to shorten life; in Mr. Nunn's book it is used as equivalent to carcinoma, and though he would doubtlessly claim that the word is never used otherwise by medical men, yet it is distinctly not advisable to employ a word which is capable of this double meaning. The various questions relating to the disease, such as regional frequency and age liability, are somewhat briefly discussed. The cases are of interest and the 11 plates represent sufficiently accurately the microscopical appearances of sections of carcinomata.

A Manual of Pharmaceutical Testing. By BARNARD S. PROCTOR, F.I.C. Second edition. Published at the offices of the *Chemist and Druggist.* 1899. Pp. 186.—No one can dispute the excellence of the purpose of this volume. It is to instruct the pharmacist so that he may be able to test his chemicals occasionally to see that their quality is up to the required standard. The processes are, of course, familiar to those who make a special study of analytical chemistry, but the present volume is restricted in its application to the ordinary contents of the pharmacy. In this way the pharmacist is not burdened with a number of analytical details in regard either to manipulation or to method, but he will find just what he wants and sufficient to satisfy him as to the purity and strength of his drugs. The work is in accordance with the British Pharmacopœia, 1898.

A Laboratory Manual of Physiological Chemistry. By ELBERT W. ROCKWOOD, B.S., M.D., Professor of Chemistry and Toxicology in the University of Iowa. Philadelphia, New York, and Chicago: The F. A. Davis Company. 1899. Price $1.—This is essentially a book for experimental work and is evidently the outcome of laboratory experience. The experiments are mostly of a simple character, and when detailed experiments are necessary they are described in small type for the benefit of advanced students. The book affords a very clear and experimental course of physiological inquiry. We notice that in describing Pettenkofer's test for the biliary acids the author warns the students not to overheat the test mixture for fear of the cane sugar charring. We have again and again pointed out that this difficulty may be completely avoided by substituting glucose for cane sugar in the test. The book is excellently printed in bold clear type on toned paper. Occasionally the pages are interleaved with blank sheets for the purpose of making notes, the utility of which arrangement is doubtful or is seldom taken advantage of. The illustrations are decidedly good and true and relate chiefly to urinary deposits, casts, and absorption spectra. The book is an excellent practical elementary guide to the study of physiology.

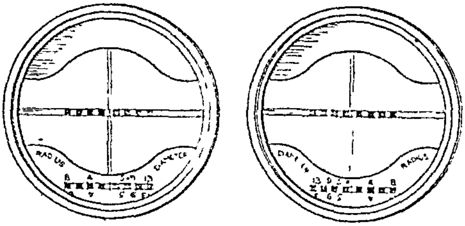
Architectural Hygiene. By BANISTER F. FLETCHER and H. PHILLIPS FLETCHER. London: Office of the *Builder.* 1899. Pp. 249.—This is a reprint of a series of articles which appeared in the Students' Column of the *Builder.* It is a small work and the descriptions of the different processes involved in applied sanitation are necessarily sketchy. This is the case particularly with the sections on sewage disposal, heating, and ventilation. The chapters on construction in regard to drainage, water supply, and building are excellent. The authors are wrong in attributing the plenum system of ventilation of hospitals to Mr. Henman of Birmingham. The system was introduced by Mr. Key of Glasgow and was applied by Mr. Henman to the General Hospital of Birmingham, of which he was the architect. The book covers a remarkably wide ground considering the space at the disposal of the authors. It gives a very good general idea of the way in which sanitary knowledge should be applied. An important feature in the book is the number of excellent illustrations which assist the authors very materially in describing the fittings and apparatus concerned in sanitary construction.

New Inventions.

AN IMPROVED METHOD OF EYE-MEASUREMENT.

THE primary purpose of the small instrument described below is to quickly determine and accurately record the relative position to each other of the centres of the two pupils of the eyes in a patient under examination. That this point is not an immaterial one will be generally admitted, especially in connexion with the estimation of refraction, as in order to obtain the most efficient results with spectacles it is essential that the position of the centres of the lenses should accurately correspond with the visual axes; and also that in any subsequent examination for the object of comparison, the correcting lenses should assume precisely the same position as on the former occasion. Without some such means as this instrument affords, the exact centring of the lenses must always be one of slight uncertainty and guesswork. There are *subjective* modes of attaining this object, but they are not so speedy, and they are greatly dependent upon the quality of the intelligence of the patient.

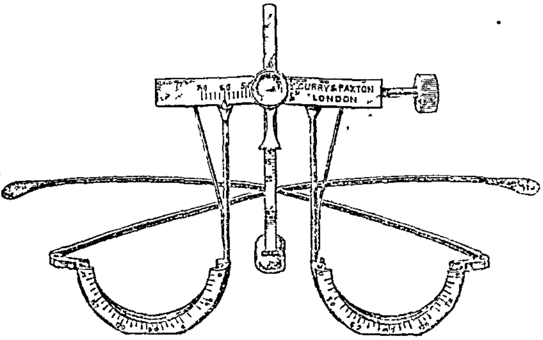
FIG 1.



Full size.

For several years I have constantly employed the discs (*Fig. 1*) *for this* purpose, and I have found them to be most satisfactory, but I have lately been able considerably further to extend their scope of usefulness. This is done by supplementing them with a double scale, marked in millimetres. One of the scales, which is stamped in red and is only half of what the complete scale would be, records the *diameter* measured from the central point; the other scale, in black, and which is complete, indicates the length of *radius* or absolute distance from the centre. The repetition of the scale in fuller detail below is simply to facilitate measurement, and the numerals duplicated in reverse enable the readings to be easily made at any position of rotation in the trial frame. The millimetre intervals are alternately coloured and blank so that they may be more clearly seen. The discs must be used in combination with an adjustable trial-frame, such as the one figured here (Fig. 2), also made for me by Messrs. Curry and Paxton; it is on the principle of that originally described by Mr. Lindsay Johnson.[1]

FIG. 2.



The diameter scale (red) permits of the measurement of the size of the pupils, relatively to each other as well as separately; it also allows of the estimation of any abnormalities in the shape or size of the pupil due to congenital, pathological, or operative causes. In addition, it enables the size of the cornea to be measured. The *radius* scale (black) furnishes a precise means of indicating the position, the shape, and the extent of any markings or alterations in the cornea, whether situated on its surface, in its substance, or in structures lying behind it or adjacent to it. It is also of use in observing the progress of inflammatory processes in the cornea by noting their increase in area or rate of absorption. Another mode of employing it is to gauge the extent and direction of deviations of the axis of the globe from that of direct vision, when caused by muscular action or by displacement due to the presence and growth of tumour formation. In the same way the limit of muscular excursions of the globe in various directions may be noted, and compared with similar observations at later periods.

The general mode of use is simple. A pair of trial-frames with the discs inserted in the usual position of cylindrical lenses is placed on the patient, who is seated at about the distance of a metre in front of the surgeon. The patient must gaze steadily forwards at a point corresponding with the bridge of the nose of the examiner, who then, by screwing the horizontal and vertical adjustment racks, brings the centres of the cross-bars of the discs opposite the centres of the patient's pupils. The two indicators of the trial-frame are then read off and noted. This gives the position of the pupil-centres, and the extent of their separation from each other. It also indicates approximately the position which would be required for spectacles to be used at "reading" distance. There is no difficulty in similarly obtaining the proper adjustment for "distance" spectacles, as at six metres the bright white metal of the cross-bars is distinctly seen against the darker tint of the eye behind it.

Further measurements when required may afterwards now be made. The size of the pupil is found by comparing the position of its edge with the number of intervals it extends to on the red bar and referring to the adjacent duplicate scale for the figures. The axis on the "cylinder-part" of the trial-frame at which this diameter is obtained should at the same time be noted. The size of the cornea is obtained in the same way. Not only may the size and general shape of the pupil be thus correctly remembered, but the position and extent of irregularities due to adhesions or malformations, may also be represented and even mapped out, by doing so on a chart such as that ordinarily used with a perimeter The other scale (black) is employed in a similar manner for obtaining the actual size and shape of corneal alterations, the position of which is found by noting their distance from the centre and also the axis in the frame at which it is read. The extent of deviations and also excursions of the globe may be recorded and compared, by noticing on the radius scale how closely the corneal margin approaches towards the central point in the particular axis. The corneal diameter must also be ascertained in conjunction with this in order to make such a comparison of any value.

In brief summary the discs enable accurate record to be made of: (*a*) the position of the pupil centres, whether at a near distance or further off; (*b*) the individual and relative size

THE LANCET.

LONDON: SATURDAY, MARCH 3, 1900.

WE know the effect of the mind upon the body to be exceedingly great. In times of epidemic, it is the anxious, the nervous, and those who are depressed and troubled with fear who the more readily fall victims to the prevailing disease. Such receptivity determines the outbreak of illness, and may possibly facilitate the spread of other maladies than infectious ones. There can be no doubt that the news from the seat of war has until quite recently had a very depressing effect on the minds of most people of this country. How far has such depression contributed to the spread of influenza and other diseases? Statistics on this point, were it possible to obtain them, might be very instructive. The reverses which our arms suffered during the first three months of the war coincided with an exceptional prevalence of sickness. Of course, it may very justly be urged that the coincidence can be explained by the simultaneous epidemic of influenza and by the wintry season. But if the splendid success with which our arms have been crowned during the past two weeks is maintained, and if there should be at the same time a marked improvement in the public health, the question may fairly be asked whether the abatement of illness is not in part due to psychological causes.

If we go about our business with a heavy weight on our minds, with our thoughts distracted and troubled by deep anxiety and apprehension, do we not tend towards a morbid condition that renders us especially susceptible to disease? The answer is certainly yes. And there is at least one evil influence from which we might have been spared and against which we may well be warned, for we are not yet out of the wood. Much unnecessary revulsion of feeling has been produced by the false presentation of war news. A reverse is difficult to endure, but when it follows immediately on confident affirmations of near victory it is infinitely worse. To fail is bad enough, but when such failure is preceded by the exultation of a supposed victory the shock and the revulsion of feeling are much more trying and intense. Therefore we should take warning by the past, and not allow ourselves to be carried away by sensational and badly sifted information which too often has to be contradicted on the morrow. It requires great coolness and great sobriety of judgment to read, to analyse, to weigh, and to dissect the very confusing and contradictory news which we receive from the seat of war. Those who are gifted with a judicious power of perception will avoid the extremes of exultation or depression. This week we run the risk of over-exultation, just as formerly we were exposed to the risk of too deep a depression. All these extremes must be avoided. Much of the misconception which has arisen in England is due to the fact that the war in South Africa has been thoughtlessly considered in the light of the history of great European wars. The nearest precedents to the present war that can be found in modern European experience are the wars of the Turks against the Servians and the Montenegrins, and the campaigns of Austria in Bosnia and Herzegovina. Had we taken the history of these wars to heart we should have realised that victory was only to be obtained by the employment of vastly superior forces, and should have avoided surprise and disappointment at our early failures.

That there should be complete confidence in ultimate success is only natural when we consider the valour of the British soldier, how vast are the resources of which we can dispose, and how changed the whole face of our prospects now is by the surrender of General CRONJE and the magnificent relief of Ladysmith; but, in the meanwhile, let us practise the virtue of patience. It will be time enough to exult when the war is definitely concluded in our favour. We shall lose nothing by patience and may avoid disappointments that are demoralising to the mind and injurious to the body. Let us, though we are now on the winning side, continue to search out our shortcomings: let us not forget the days of adversity and the lessons which they taught. The man of a calm, dispassionate mind who recognises that there are faults on both sides, that there is need of reform in all countries, that we do not as a birthright possess every virtue under the sun, and that consequently adversity may be but a friend in disguise, even as he has been able best to resist the depressing effects of the past crises will also be able best to comport himself with moderation in the hour of victory. Finally, we may repeat that these simple, obvious principles, which are none the less hard to observe because they are so simple, are not only medicine for the soul but also physic for the body.

◆

THE advance of sanitation in certain States of the American Union has of recent years been indeed remarkable, and the example which Massachusetts, for instance, has set in the direction of scientific research in matters concerned with water and sewage purification might profitably be followed by many European countries, not omitting Great Britain. It is, however, to be regretted, more particularly so if regard be had to the expansion of America and to the probable creation ere long of an American empire beyond the seas, that this great republic does not at present feel herself justified in dispensing with quarantine methods and in relying upon her sanitary machinery for the control of exotic disease.

The Treasury Department, under the advice of Surgeon-General WALTER WYMAN, of the Marine Hospital Service, have recently issued certain additions to their quarantine regulations for preventing the plague which are well worth study. In the first place, it is enacted that vaccination should not be practised on persons at, or *en route* from, places infected with plague inasmuch as such vaccination "increases the liability to plague infection and by inducing fever and swollen glands tends to confuse diagnosis at the port of arrival." This prohibition would, we surmise, hardly be enforced had the patient been exposed to infection from small pox, as the presence of small-pox on board a ship is little less disastrous than is bubonic plague. Throughout the new regulations much use is made of the members of that excellent organisation the Marine Hospital Service, and baggage, even though coming through a plague-infected district, will not be rejected in America if it is duly sealed by a medical officer of this service and arrives with its seal unbroken. Passengers, however, coming from a suspected or infected locality who desire to take passage at an uninfected port are to be kept under observation for 15 days prior to embarkation, or otherwise the vessel carrying such passengers will be considered as coming from an infected port, and this even if no case of plague has developed on the journey. The baggage of such passengers is to be disinfected before being sent on board. When plague is prevailing in a port it is forbidden to tie up a vessel to the dock and no ropes likely to afford passage for rats are to be allowed. It is, moreover, enacted, with a view to the prevention of the spread of plague by mammals, that dogs, cats, monkeys, mice, and the like, are not to accompany passengers as pets. If they do so the animals are liable to a quarantine period of 15 days. Under the regulations relative to the American ports we note that pilots, Customs officers, and agents, or other persons whose official duties may cause them to board incoming vessels, may be deemed and treated as passengers or crew and can be detained in quarantine sufficiently long to cover the period of incubation of plague. As to the examination of passengers, it is provided that in dealing with infected or suspected vessels all clothes likely to interfere with the examination of glandular regions are to be removed, female inspectors being of course provided. In the treatment of vessels suspected of plague it is laid down that no person from an infected or suspected place shall be admitted into the United States until 15 days shall have elapsed under observation, but such observation may take place at the port of departure, at sea, or at the port of arrival. In the case, however, of a first-cabin passenger, who is certified by an officer of the Marine Hospital Service not to have been exposed to infection for 15 days immediately prior to embarkation, entrance may be allowed without detention. All passengers other than first-cabin passengers are to be bathed and their clothing disinfected before landing, and if the crew, in the opinion of the quarantine officers, have been exposed to infection, similar measures are to be taken with regard to them. Extensive operations are contemplated in reference to the baggage from infected places, and its disinfection is provided for either at the port of departure or that of entrance. The quarantine officer is given enormous discretionary power in relation to vessels of this class and in the event of a vessel carrying passengers but having no surgeon on board the ship may be quarantined with all on board for the full 15 days from the completion of disinfection.

The methods adopted for dealing with plague-infected vessels would be regarded in this country as altogether impracticable, but it has, of course, to be remembered that the internal sanitary machinery of America is behind that of this country. The sick and suspected cases are to be isolated and the remainder of the passengers are to be segregated in groups; while, if practicable, antiseptic serum is to be used as a preventive measure. All are to be detained under observation for 15 days from the "last possible exposure to infection" and are to be inspected twice daily by the physician in charge. As a preliminary measure all accessible parts of the vessel are to be fumigated with sulphur dioxide, with a view, it appears, to the destruction of the rats on board, and such disinfection is to be performed by daylight in order that small boats around the vessel may be able to prevent the escape of rats. The holds of infected or suspected iron vessels carrying cargo are to be fumigated for 24 hours with sulphur dioxide, and if the hold is without cargo it is to be thoroughly washed with perchloride of mercury. It will be of great interest to observe how, in the most unfortunate event of plague extending and many ports becoming infected with the disease, America will be able to carry out her scheme in its entirety. Imagine, for instance, such regulations being in force in this country and Calais infected with plague. How would they work? We note, however, that there are many discretionary clauses in the regulations, and we infer that the rules are a little theoretical. It will be seen, by the way, in a communication from our New York correspondent that 15 officers of the United States Marine Hospital Service have been detailed for service at European seaports. They will take note of vessels bound for the United States and will keep the Bureau informed as to the sanitary condition of the cities in which they are stationed. This is a sound idea.

In a pamphlet entitled "On Life Assurance Inquiries respecting the Use of Alcoholic Stimulants"[1] Sir DYCE DUCKWORTH points out that, with the exception of the inquiry regarding the tendency to tuberculous disease in any individual presenting himself for life assurance, there is no question of greater importance, or more difficult to find the exact answer to, than that relating to the employment of alcoholic drinks. There is seldom difficulty in recognising the indications presented by candidates who indulge freely in stimulants, yet even in some of these instances a good deal of experience is needed on the part of the medical examiner and some moral courage to determine the matter and manner of his questions. But in a large number of candidates the difficulty is to determine exactly what constitutes a departure from strict moderation in the use of alcoholic liquids. We fully support Sir DYCE DUCKWORTH's contention that not only great clinical experience and wide knowledge of the habits of different classes of people are requisite to qualify medical examiners in prosecuting their inquiries, but also that there should be a personal knowledge of the character, qualities, and effects of different varieties of alcoholised liquors.

It has been argued that the practitioner who is a lifelong abstainer is probably less well equipped than others to judge quite correctly in all the bearings of this matter owing to his personal inexperience. In the debate which followed upon Sir DYCE DUCKWORTH's paper, this opinion was strongly repudiated by Dr. HINGSTON FOX, who, as an abstainer himself, submitted that the experience by which these cases are judged is derived from the observation of men in general, observation which comes to medical men every day in countless forms. This is undoubtedly true up to a certain point, but at the same time we cannot help feeling that a strict abstainer from alcohol can hardly resist a certain bias against habitual use of alcoholic drinks, though used to an extent which the majority would regard as moderate. The difficulty lies mainly in deciding what is to be regarded as "moderate drinking," or, in more scientific phraseology, as the "physiological limit." The statistics of those assurance societies which have two departments—one for those who abstain and the other for those who do not—were severely criticised by Dr. DE HAVILLAND HALL, who remarked that when the position held by total abstainers in such offices is compared with that held by the moderate drinkers everything is in favour of the total abstainer, because the ordinary class includes those who drink moderately and also those who drink immoderately. Clearly such figures will not assist us to draw a comparison between the effects of moderate drinking and "immoderate moderation," as Sir DYCE DUCKWORTH expressed it. The medical adviser is called upon to consider in detail the circumstances under which the proposer is living, and to estimate as best he can whether these circumstances are likely to be continued and become disastrous, or whether, either at a medical man's suggestion or from some other cause, the proposer is likely to amend his ways, to reduce his supply, and so to prevent any evil effect. Only after prolonged experience can any reliable opinion be formed. We believe that the vast preponderance of medical opinion will be with Sir DYCE DUCKWORTH in the belief "in the value of a truly moderate quantity of alcoholic liquor in some form consumed with a meal, in no routine fashion, however, but according to the demands of a disciplined appetite"; while no medical man will dissent from the view that total abstinence should be prescribed for those persons with morbid or irregular craving for alcohol, whether this be inherited or acquired. There can also be no doubt that those individuals who have habitually overstepped the "physiological limit" should not be rated as first-class lives. This morbid condition is shown by premature ageing, a tendency to obesity, and more especially by evidences of vascular changes such as small dilatations of superficial vessels and progressive arterial sclerosis long before the natural period in which such senile decay may be expected. Other signs are early whitening of the hair, and not seldom, through errors of hepatic and other metabolism, some degree of glycosuria is apt to occur. The kidneys are not infrequently involved in the sclerosing process.

---

[1] A paper read before the Life Assurance Medical Officers' Association on Nov. 1st, 1899, by Sir Dyce Duckworth, with the discussion that followed.

As a practical outcome of his remarks Sir DYCE DUCKWORTH urged on the consideration of the members of the Life Assurance Medical Officers' Association the following rules of practice in dealing with life assurance inquiries into the use of alcoholic liquors: (*a*) that care should be taken to ascertain as fully as possible the nature and amount of stimulants taken daily by each candidate and the particular hours in the day when they are consumed; (*b*) that an attempt should be made to form an accurate opinion as to the effects of the candidate's habits on his bodily textures and nervous capacity, having regard to his mode of life, his environment, and peculiar temptations; and (*c*) that in cases of drinking in the degree of immoderation, if there is no prospect of decided amendment of the habits an extra premium should be demanded in view of a premature onset of degenerative bodily changes. These suggestions will doubtless commend themselves to all those who have to consider applications for life assurance. Each proposal will have to a great extent to be considered on its merits, but a general line of practice, such as the above, will be sure to carry with it the confidence of the directors in the action of their medical advisers whilst avoiding any injustice to proposers.

◆

THE Lunacy Bill introduced by the Lord Chancellor during the present session of Parliament is in form and substance the Bill of last year except for the omission of certain important matters. Amongst the omissions is the provision for making compulsory a scheme of pensions for medical officers, attendants, and other servants of asylums. This has been dropped out of the present Bill owing to the opposition of the county councils to the superannuation scheme proposed in the Bill of last year. The Bill of 1898, re introduced in 1899, was a decided improvement on that of the previous year, inasmuch as it rendered compulsory the granting of superannuation allowances which were merely optional under section 280 of the Lunacy Act of 1890. Prior to the session of 1898 a petition had been presented to the Lord Chancellor by the Medico-Psychological Association of Great Britain and Ireland, this petition being signed by over 4000 officers, attendants, and servants of public asylums, the result of which was the insertion of the pension clause above referred to. This clause was subsequently dropped owing to the opposition offered, and its omission from the Bill now before the House is a serious defect. It leaves a grievous difficulty and injustice without remedy. On a former occasion we pointed out the injury which such a measure would inflict on the asylum service of the country, for this would be the only public service in which it would be possible for an officer to be cast adrift in his old age after a long and arduous service without any provision other than the savings he might have succeeded in accumulating from an income which is seldom other than small. The provisions for the reception and treatment of incipient and curable forms of insanity reappear in the same form and possess the same commendable features as before. The facilities given for placing suitable cases under care in private homes for the period of six months allowed by the Act, and without the tedious formalities previously in vogue, will afford important aid in the future treatment of incipient and unconfirmed cases of insanity. But we must point out that the reduction in the valid duration of an urgency order from seven days to four days would impose certain practical difficulties in the way of fulfilling the requirements of the Act in localities where a magistrate is not readily found, and might thus defeat the object of such orders. The alteration, while rendering the working of the Act irksome, will probably have no effect in preventing abuse of the liberty of the subject. It is clear that strenuous opposition should be offered to the Bill in the interests of asylum medical officers and other workers. The machinery of the Medico-Psychological Association has in the past proved effective in promoting reform and in diminishing abuse, and in these labours the Psychological Section of the British Medical Association has loyally coöperated. We may expect that both bodies will unite in an attempt to have restored to the Bill the clause making provision for pensioning the medical and other officers of asylums. The position and status of the public asylum service and the grave responsibilities entrusted to the hands of its officers alike demand that a high level of professional attainments and of character should be a *sine quâ non* to qualify for the service, and it is in accordance with the fitness of things that legislation should have for its object the maintenance of such a level. Its failure to do so can only invite disaster in the future.

Annotations.

"Ne quid nimis."

THE LIABILITY OF THE BAD BOY.

The case of Eady *v.* Elsden, heard recently by Mr. Justice Ridley and a jury, was curious in more ways than one. In the first place, it is said to have been the first action ever brought by a schoolmaster against his pupil for damage done by the boy to the master's property; and, in the second place, the boy set up unsuccessfully the defence that he was insane when he did the act complained of and that the master undertook the charge of him with the knowledge that he was mentally affected and failed to exercise proper discipline and control over him. The facts seem to have been that a boy, of quick intelligence but of extremely turbulent behaviour, was sent to a school the master of which advertised himself as prepared to undertake the charge of troublesome boys. From this school he ran away and having been brought back set fire to the school-house which was burnt to the ground. The fire office seems to have refused payment of the insurance on the ground that the master was responsible for the fire, and he having ascertained the real author of it brought an action against the boy in order to establish clearly his own position in the matter. The defence of insanity is one frequently raised when a person is charged criminally, but it is not so common when a person is only sought to be made liable civilly, for it may injure the defendant in the pursuit of his daily calling to have proved, or tried to prove, that he was once, at all events, not responsible for his actions. In Eady *v.* Elsden the defendant, though still a minor, was endeavouring to earn a livelihood in the employment of a cycle-maker; he had a reversionary interest in certain property enjoyed by his mother, and that the infant is at law liable for wrongs committed by him is as certain as it is that the parent is not responsible for them. That young Elsden should have failed to prove himself insane is not surprising, for his mother who was his principal witness on this point does not seem to have been able to quote any medical men who were prepared to take a serious view of her son's admitted eccentricities. That he was given to breaking windows and that he had frequently injured his mother's watch was not perhaps considered by medical men, if they were consulted on the subject, symptomatic of serious mental derangement in an otherwise intelligent boy. On the other hand, the plaintiff had on one occasion with commendable prudence consulted a medical man with regard to his pupil owing to some incident that seemed unusual and demanded punishment, when the medical man found nothing to prove that the lad's mind was affected; while on another occasion the late Sir Russell Reynolds, who had seen the boy after he had run away from school, apparently said that he might safely be punished by whipping like any other troublesome pupil. The jury consequently were able to say that young Elsden was not insane when he set fire to Mr. Eady's house and, further, that there was nothing special in the arrangements made with regard to him that need prevent Mr. Eady from recovering. Mr. Eady is to be congratulated upon his success. It would have been a serious matter for him if it had been proved that he undertook, with his eyes open, the charge of boys whose mental condition demanded medical rather than educational care and neglected to take precautions with regard to them.

THE RECENT FATALITY IN SCARBOROUGH HOSPITAL.

A little girl, aged five years, was taken to the Scarborough Hospital on Friday, Feb. 9th, by her mother, who stated that the child had a bead in her ear, "the club doctor" having seen the patient and having made an unsuccessful attempt to remove it advised that the child should be taken to the hospital where she could be "held by nurses" as she was so restless. At the hospital the patient was seen by Mr. F. Bawtree (assistant house surgeon), who found that as she would not keep still it was impossible to make an examination of the ear, so he recommended that she should return the next morning to have chloroform administered when a thorough examination could be made. This was agreed to; the mother, who received instructions as to the feeding of the child, brought her again the next morning (Feb. 10th). Dr. M. D. Wood (senior house surgeon) gave chloroform from a small drop-bottle upon lint. The patient was under the influence of the anæsthetic in about six or seven minutes. Mr. Bawtree examined the left ear which was found to be full of clotted blood; this was syringed out and a clear view of the membrana tympani was obtained (it was healthy and there was no rupture); no foreign body was seen. During the time this examination was in progress the patient took the anæsthetic without the least bad sign, the pupils were contracted to pin-points, the breathing was rhythmical, the patient's face was a good colour, and the pulse was regular. Mr. Bawtree having finished his examination requested Dr. Wood to look at the ear, and in the meantime took charge of the patient as far as the anæsthetic was concerned, but no more chloroform was given. Dr. Wood having examined both ears suggested that the left ear should be again syringed as it still contained a fragment of blood-clot. While the syringe was being filled the patient made an attempt to vomit, a small quantity of mucus being expelled from the nose, directly after which it was noticed that the child was cyanosed, the respiration ceased, the pupils began to dilate, but the heart still continued to beat. The urgency of the situation was at once recognised and the child was placed with her head over the end of the table and the body was raised, a finger was passed into the patient's mouth to the back of the tongue and both jaw and tongue were brought forward. Artificial respiration was at once resorted to and the respiratory passages allowed a free entrance of air to the lungs. After this had been in progress for about three-quarters of a minute the patient's condition improved, the colour of the cheeks became more natural, and the pupils began to contract. This improvement, however, was only temporary, and though the artificial respiration was continued in the same way slowly and deliberately the patient sank back into the former condition and died. Brandy was injected into the præcordium and the faradaic current was applied, but without any good effect. In all a little under one drachm of chloroform had been used.

A post-mortem examination was made; the veins of the neck were found to be congested and all the organs of the body were found to be healthy. The wall of the left ventricle of the heart was hypertrophied but all the valves of the heart were competent; there were no signs of disease. The heart weighed five and a quarter ounces. The borough coroner, Mr. George Taylor, held an inquest, and in summing up said he considered that the case was one in which there was necessity for the administration of chloroform, that every care had been used in the administration, and that there was no negligence on the part of anyone. The jury brought in a verdict in accordance with the medical evidence that "Death was due to failure of the heart, following on temporary asphyxia caused by vomiting, consequent upon administration of chloroform." This case is typical of many deaths due to chloroform, especially of fatalities among children. It is noticeable that the administrator of the chloroform handed over his task to a second person. This is often inevitable in hospital practice but is not without danger as the second administrator is often in doubt as to the stage of the anæsthesia. The failure of circulation associated with the onset of vomiting is a common phenomenon which is at present but imperfectly understood. The true causal relation is certainly doubtful, but the asphyxial condition which is described in the present case possibly was the factor determining cardiac failure. There appears to have been impediment to respiration which, imposing a severe strain upon a debilitated heart, taxed it beyond its power. The probability of a weakening of the heart (acute dilatation) by rapid chloroformisation with imperfect ventilation of the lungs, which takes place in many cases, should always be borne in mind as establishing a state of the circulation predisposing to cardiac failure.

HOW TO SPREAD INFECTION.

A VERY useful reminder was administered to the public recently through the publicity given in the newspapers to a case heard at the South-Western Police Court, in which the mistress of a household was summoned under the 126th section of the Public Health Act of 1875 for exposing in a public place a servant in her employment when suffering from a dangerous infectious disorder and particularly for placing her in a public conveyance. The mistress had sent her servant who was ill, accompanied by a fellow-servant, to a medical man. He certified the sick servant to be suffering from diphtheria and advised her removal to the Fever Hospital at Tooting. There appears to have been some conversation between the two servant girls, the medical man, and his partner, as to the comparative merits of the outside of a tram-car and the interior of a cab as conveyances, and the medical man himself seems to have suggested an ambulance. How far this conversation was reported to the mistress by the two servants was not elicited at the hearing before the magistrate, but in the end the mistress, who at least had heard what was the matter with the patient, gave the two servants five shillings and suggested that they should go to the hospital in a cab. The house surgeon very properly detained the cab for disinfection and was no doubt to some extent responsible for the matter coming to the ears of the local authorities who took out the summons. On hearing the whole of the above facts and taking into consideration that the patient was of full age, the magistrate decided that he could not find that the mistress had been in charge of the person suffering and had exposed her within the meaning of the Act and he dismissed the case. He, however, made no order that the unsuccessful prosecutors should pay the defendant's costs, doubtless marking thus his opinion that an employer, presumably of better education than her servants, acting as the defendant had done had incurred a moral if not a legal responsibility. With this view every thoughtful person will concur, and the thoughtless should realise, on reading the report of the case, that the defendant who was summoned escapes a fine but does not go scot free. The costs of a defending solicitor and of witnesses, to say nothing of the anxiety and loss of time, are substantial items, and from a pecuniary point of view, if from no higher motive, it is wiser to keep well within the law than merely to avoid overstepping its limits. Ignorance of its provisions is no defence for breaking it, and this rule involves no hardship where the exercise of ordinary good sense would lead to much the same conclusion as the perusal of the Public Health Act.

THE VESTRIES AND THE SNOW.

THE decision arrived at by Mr. Curtis Bennett in dismissing a summons against the Marylebone Vestry for failing to remove snow is a little disappointing. The complainant, Mr. Joseph Hurst, a barrister, appeared in person, and his own evidence and that of his witnesses, among whom was Lord Robert Cecil, Q.C., were not disputed or contradicted. In the street in which Mr. Hurst lives the snow which fell on Feb. 2nd and 3rd remained unremoved, and was supplemented by the subsequent fall on the 10th, until it melted away on the 20th, the pathways being cleared but the snow from them being left heaped in the gutters. It was argued that by more vigorous measures and by more liberal payment of its workers the vestry might have cleared it away, which it was by law bound to do. On the other side it was proved that labour was difficult to get, that after the first effort, at all events, a wage equal to that paid by other vestries was offered, that 1800 tons of snow were removed, and that the vestry had spent on the work £3260, a sum equal to a rate of three-sevenths of a penny in the pound on the rateable annual value of the parish. It was also urged that by the Act[1] under which the proceedings were brought the vestry was only bound to sweep and cleanse so far as was reasonably practicable and that it could not be called on to attempt impossibilities or be punished for failing to achieve them; and this view the learned magistrate took in dismissing the summons, which, however, he did without allowing costs to the otherwise victorious vestry. It seems to us that Mr. Hurst deserved more success. He may have injured his cause by putting his requirements too high or by suggesting the adoption of methods not suited to the district which he represented. The use of salt, which he commended, to thaw the snow is very objectionable where it can be avoided, and it is not largely employed anywhere. Marylebone was not the only district in which loud complaints were to be heard after the recent snowfall; they were heard all over London, and they are invariably heard when any serious fall of snow takes place. It is quite possible that the remedy may not lie in the employment of a very much larger body of men or in the expenditure of very much larger sums of money than are now usual, although parsimony in such emergencies is to be deprecated. The cure probably lies in the better organisation of the labour with a view to its prompt application, in the better supervision of the gangs to ensure their doing their full measure of work, and in preparing some permanent apparatus in each district for the liquefaction of the snow, so that the carts employed may do as much work as possible in the shortest possible time. It was said recently on the death of a prominent New York citizen that until he took in hand the cleansing of the streets of New York the removal of snow had always been regarded as presenting insurmountable difficulties. Perhaps some day a London vestry will find an organiser whose example will instruct other vestries. Meanwhile opinions differ as to the desirability of throwing on the local authorities the duty of removing snow from the side walks—a duty which in many cases lately they have carried out inadequately, and which, as Mr. Hurst observed, the private citizen is now not only not called upon but is not permitted to perform.

[1] Public Health (London) Act, 1891.

HOSPITALS IN NEW SOUTH WALES.

THE fourth report of the Royal Commission on Public Charities in New South Wales deals with the hospitals of that colony. It is a Blue-book published by the Government printers in Sydney and contains a total of 254 pages, 55 of which are devoted to the report itself and the remainder to the minutes of evidence and appendices. The Commission was appointed in November, 1897; as recorded in this volume it held 39 meetings from April 14th, 1899, to Sept. 13th, 1899. There are in the colony 108 hospitals which are subsidised by the State, one maintained entirely by the State, and five not subsidised. To these have to be added five institutions for lying-in cases, three of which receive Government aid. These 119 institutions provide for 3422 beds—namely, about two and a half beds per 1000 of the population, and in addition there are 1383 hospital beds in the Government Asylums for the infirm and destitute, so that in all there is accommodation for 4805 patients, being a ratio of about three and a half beds per 1000 of the population. The total expenditure in 1898 was £145,424. The receipts (less the bequests which were invested by the Sydney and Prince Alfred Hospitals and consequently were not available for expenditure) amounted to £142,686, towards which the Government contributed £83,355. Of the latter sum £20,910 were for the maintenance of the hospital at Little Bay. The cost of the treatment of the sick poor in the Government Asylums of the Infirm and Destitute is not taken into account in these figures. Of the total revenue of the subsidised hospitals (less the bequests referred to), the Government contributed 51 per cent. in 1897 and 51·3 per cent. in 1898; whilst the contributions from the public in the form of subscriptions and donations in three years amounted to only 33 9 per cent. and 33·5 per cent. respectively. The total number of in-patients treated in the subsidised hospitals was 22,158 in 1897 and 23,832 in 1898. The number of in-patients treated in 1898 by the hospitals not subsidised by the State (excluding lying-in homes) was 3292, of which 1665 were dealt with at St. Vincent's Hospital, Sydney. Including the number treated at the Coast Hospital there were thus 29,818 patients who received hospital care in the colony in 1898, an increase of over 76 per cent in the last ten years. The general hospitals in the metropolitan area of Sydney are: (1) the Sydney Hospital (including the Ophthalmic Branch) (318 beds); (2) the Prince Alfred Hospital (236 beds); (3) St. Vincent's Hospital (175 beds); (4) the Glebe Hospital for Children (64 beds); and (5) the Coast Hospital (286 beds). In addition to these there are (*a*) the convalescent hospitals (at least 100 beds); (*b*) the suburban hospitals (152 beds); and (*c*) special hospitals for maternity cases and diseases of women (approximately 181 beds). The majority of the witnesses examined by the Commission stated that there was great pressure on this accommodation, but on the other hand some witnesses well qualified to form an opinion (Dr. Ashburton Thompson, Dr. Charles Mackellar, and Dr. Sawkins) saw no need for any immediate increase. Sydney Hospital has been in active operation ever since its foundation in 1811. The buildings in which the patients were housed were, with the exception of one detached block, demolished in 1876, and temporary wooden structures were provided so that the work of the hospital could be continued until the completion of the new buildings in 1892. The new hospital is on the pavilion system, contains 12 wards, and has "bed accommodation" or 241 patients. It has a "spacious and well-arranged" pathological department, with reference to which the following remarkable observation is made in the report: "It appears to be unnecessary that pathological or bacteriological inquiries, except for clinical purposes, should be undertaken at this hospital, to which no medical school is attached, and anything in the nature of bacteriological research would appear to be outside the functions of an institution of this character." The ophthalmic department at Moorcliff has 69 beds. The number of in-patients in 1898 was 3904. The Prince Alfred Hospital was the outcome of a movement initiated in 1868 to give expression to the gratitude of the public at the recovery of Prince Alfred (the Duke of Edinburgh) from an attack made on his life. By a special Act of Parliament it is affiliated to the University of Sydney. The staff of the hospital includes a medical tutor, with a view of assisting students in their clinical work. The number of in-patients treated in 1898 was 3706 and of out-patients and casualty cases about 12,500. St. Vincent's Hospital is essentially a private institution, under the care of the Sisters of Charity, and under the immediate direction of the mother rectress of the Order, but it takes rank after the large public hospitals (the Sydney and Prince Alfred) owing to its large size and the number of patients for whom it makes provision. It was first opened (with eight beds) on a site different from the present one in 1857. It now contains seven main wards and 20 private wards. In 1898 there were 1665 in patients, and there were also 7644 out-patients who made 22,700 attendances. The Coast Hospital, built during an epidemic of small-pox in 1881 and 1882, is essentially a Government institution. In 1883 lepers were sent there and were accommodated in temporary structures till 1890, when a regular lazaret was built. Since 1884 it has been used as an overflow hospital for the metropolitan district, and even for the treatment of infectious disease. Among the many subjects dealt with in the report are the treatment of sickness by friendly societies and provident dispensaries, the necessity for a free dispensary, accommodation and treatment of venereal disease, the pay or part-pay system in hospitals, out-patients, and private hospitals. On the subject of hospital abuse the report says: "The evidence shows that the charity of the hospitals is taken advantage of by a number of persons who have no claims upon it whatever. ...... Among the more flagrant cases appear to be patients from the country who come to Sydney for operations and who escape the fees which their medical attendants in the country and those they consult in Sydney propose to charge by getting admission to the hospitals under plea of poverty." In Sydney there are about 20 private hospitals, but there is considerable difficulty in ascertaining their exact number, since they are not registered and there is no recognised or complete list of them in the medical or other directories. "The majority have established and highly creditable reputations." The report, however, recommends registration and inspection of these institutions, with a view to preventing illegal operations and other abuses.

MUMPS IN OLD AGE.

FEW cases of mumps in the aged have been recorded. Pepper[1] refers to a case of double parotitis in a lady, aged 84 years, which ran a regular course up to the sixth day when she suddenly became stuporous with jactitation and stertorous respiration. She died on the following day. In the *American Journal of the Medical Sciences*, December, 1899, Dr. H. J. Walcott, jun., has published the following case in which the age appears to be the greatest on record. A retired physician, aged 99½ years, felt chilly while working in his garden, as had been his habit. For two weeks he had not felt well and had lost his appetite, and for a few days he had been troubled with dryness of the mouth. He at once went into the house and soon after complained of his face. He vomited after trying to eat a little supper. Towards night the pain became worse and swelling appeared. He experienced now severe pain about the angle of the jaw and difficulty in opening his mouth. The right parotid gland was swollen and tender and the overlying skin was rosy. The pulse was 86, full, and strong; there appeared to be but little fever (owing to the patient's objection the temperature was not taken). On the following day the swelling was much increased, the right eye was closed, and he was delirious. He was weaker on the third day, the swelling was diminished on the fourth, and he could fully open the eye. On the fifth day the swelling was still subsiding, but he gradually became weaker and died. There were a number of cases of mumps in the town, and two weeks before the patient was taken ill he had attended a public entertainment where he came in contact with members of a family in which mumps existed. The question may be asked, Was this a case of parotitis from exposure to cold or from injury, and not one of mumps? The history of exposure, the malaise, anorexia, chill, dryness of the mouth, and course of the disease, are all in favour of the diagnosis of the latter disease.

THE ROYAL METEOROLOGICAL SOCIETY.

As this society will attain its jubilee on Tuesday, April 3rd, having been founded on April 3rd, 1850, it is proposed to observe this fiftieth anniversary in a special manner. The Council have arranged for a commemoration meeting to be held at 3 P.M. at the Institution of Civil Engineers, at which the President of the society will deliver an address and delegates from other societies will be received In the evening a conversazione will be held at the Royal Institute of Painters in Water Colours. On the following day, April 4th, the Fellows will visit the Royal Observatory, Greenwich, and in the evening will dine together at the Westminster Palace Hotel. In view of this jubilee celebration Mr. G. J Symons, F.R.S., was elected President at the annual meeting of the society on Jan 17th, but owing to illness he has since been obliged to resign this office. Under these circumstances the Council at their last meeting appointed Dr. C Theodore Williams as the President of the society.

FACTORY LEGISLATION.

THE Home Secretary has made it known that his Bill for the amendment of the Factory Acts, which he hopes shortly to introduce, will provide new machinery for bringing into force the special rules applicable to dangerous trades. It will also deal with the question of arbitration in connexion with which considerable difficulty has recently arisen. These special rules will, of course, apply to lead-poisoning in the Potteries, and we understand that the regulations are somewhat severe. When these rules are adopted the next question to be considered is how their enforcement is to be ensured. As it is, the special rules already obtaining and which were established in 1898 are frequently infringed, as is shown by the reports of recent prosecutions appearing in the daily press These infringements relate in most cases to the failure to provide and maintain sufficient and suitable washing conveniences for all persons employed in dangerous processes. In one instance it was affirmed by the lady inspector that the lavatory accommodation was inadequate. In another case a firm was summoned for employing a girl, 15 years of age, for two months in a dangerous process without a certificate of fitness, while another firm nilarly summoned for not entering the name of the employée in the health register with the consequence that she was not medically examined. Lastly, a well-known firm of potters was summoned for failing to provide overalls and head coverings for workers in the dangerous process of colour-dusting. These interesting cases were brought to light by the vigilance of the principal lady inspector of factories, and it seems to us that with the advent of still more stringent rules an increased number on the staff of inspectors will be required.

VACCINATION AND PASTEURISM IN THE DUTCH EAST INDIES.

THE information epitomised in the subjoined table is derived from the annual reports[1] of the Director of the Animal Vaccine and Pasteur Institute which is installed at Weltvreden, in the vicinity of Batavia. The Dutch have always been reputed to be a cleanly race—so much so, indeed, that the spotlessness of a Dutch interior has become proverbial—and in their Eastern possessions (where, according to a recent report, no less than 45 cwt. of quinine were distributed gratuitously among the natives in order to combat malaria) they are evidently fully alive to the advantages of sanitation and preventive medicine.

Year.	Number of calves inoculated.	Number of vaccine tubes distributed.	Percentage of successful vaccinations.	Numbers vaccinated at Institute.	Number of patients treated preventively for rabies.	Deaths among persons so treated.

* Two of the fatal cases in 1897 "were infected at the Instit itself."

STREET NOISES AND MEDICAL MEN.

A CASE of some interest to medical men was tried in the High Court of Justice before Mr. Justice Farwell on Feb. 22nd. The plaintiff, Dr. John Templer Crosbie Conry, sought an injunction to restrain the defendant, who sells fried fish, from carrying on his business in such a manner as to be a nuisance. Dr. Conry is in practice in North Kensington, and the defendant, whose name is Fox, lives ten doors away from him. Mr. Fox was wont to stand outside his shop and shout to the public the merits of his wares, in doing which he seriously interfered with plaintiff in the practice of his profession. The plaintiff on examination told how the shouting of the defendant interfered with his examination of patients. Since the writ had been issued some six months ago the shouting had diminished. Defendant was not the only person who shouted, but he was the worst. Defendant said that he came back from market at about 10 A.M. From then until noon he stood outside his shop inviting customers to buy. He then fried fish until 2 P.M., rested from 2 P.M. until 4 P.M., and then stood outside from 4 P.M. until 6 P.M. He only talked and did not shout except when there was a costermonger on the other side of the road. In such a locality it was impossible for him to make a living without calling out to attract custom. The judge said that he considered the injunction should be granted, for the defendant by his shouting made such a noise as seriously to interfere with the practice of the plaintiff. This is a sensible judgment. The contention of the defendant that he had to make a noise to attract custom is nonsense. A fried-fish shop is very far from being a retiring, coy business in itself. It exhales odours which are perfectly perceptible some 100 yards away. No vendor who has a stationary place of business need shout nor should he be allowed to do so. We must put up with the bawls of the wandering coster and of the itinerant muffin-seller, and even, we suppose, with the doleful wailing of the coal-vendor. These peripatetic tradesmen do not appeal to passers-by but to persons in houses, so that they may reasonably contend that notice must be given of their approach. But the fried-fish merchant and the seller of "stickings" should exercise their trade in quiet.

---

"BIBLIOGRAPHIA MEDICA."

AS will be seen by the letter from our Paris correspondent the first number of *Bibliographia Medica* has just been issued. This work, which has arisen like the phœnix from the ashes of the *Index Medicus*, is intended to carry on the same traditions. The amount of matter written upon medical and other scientific subjects is nowadays so great that it is impossible for any one observer to keep in touch with it all except by the aid of some such publication as this. The new venture deserves success and we offer our hearty good wishes for it to Dr. Marcel Baudouin, Dr. C. Potain, and Dr. Charles Richet, who are at the head of the executive organisation for publication.

THE CONNEXION OF THE LYMPHATIC VESSELS AND BLOOD-VESSELS.

THE interesting observations by Mr. C. H. Leaf, which we record this week, add to our knowledge as to the connexion between the lymphatic and blood vascular systems. Mascagni, Haller, and Cruikshank never allowed that the lymphatic system had any connexion with the blood-vessels, except with the large veins in the neck, but cases of such connexion have been recorded by Nuhn, Petrel, Stenson, Wepfer, Schmiedel, Vermeuil, and Meckel. The veins into which the lymphatics directly opened were the venæ cavæ, the portal, renal, axillary, internal iliac, and the azygos veins. The accuracy of these anatomists is too thoroughly known to admit any question as to the truth of their observations, even if we dismiss Lippi's descriptions as extremely doubtful. Mr. Leaf gives us further examples of this connexion between the lymphatic and venous trunks and he also shows that a direct communication exists between the small arteries in the thorax and the lymphatic vessels in that region, although the connexion is not so free as between the lymphatics and the veins.

PUBLIC BATHS.

THERE are still numberless places in these islands unprovided with public baths, and those not merely country places but towns with above 10,000 inhabitants, where there are many workers in occupations tending to make them dirty. Very few, even if we cannot say none, of the houses inhabited by the working classes are provided with bath-rooms, and in fact the same may be said of many houses in London which are not quite modern in construction, but which are let at rentals of considerably over £100 per annum. The need for public baths is specially noticeable in places where large numbers of workers are engaged in occupations such as coal-whipping, in crafts necessitating working in iron, in gasworks, in dusty trades, or, as at Deptford, in businesses connected with the slaughtering of cattle. Although a bath can be taken in a private house, however poor—for the cost of a tub that will answer the purpose is trifling—yet want of space is a serious factor. Families living in one or two rooms, and those not on th ground floor, find it difficult both to procure the water ar to get rid of it when it is done with. Therefore we thir that the establishment of public baths would undoubted be a great convenience to many a worker. In Durham ar Northumberland it is, we believe, the weekly custom for eve miner to have a warm bath, and a most salutary custom it i No arguments are needed to prove that it is more healthy be clean than to be the reverse, but those local authoriti who have yet to provide public baths might well be remind by their medical officers that the skin, to perform i function properly, should be freed from the accumulatio of dead epithelium and dried excretion which collects da by day if a bath is not taken. It is false economy on th part of a community, which is never so well off as when i workers are healthy, to shirk the provision of public baths.

PUBLIC MEDICAL SERVICE OF BRITISH GUIAN

IN the annual report for the year 1898-99, Dr. J. E Godfrey, acting surgeon-general of British Guiana, state that the health of the colony generally was fairl good in so far that there were no epidemics of severe type, but the mortality, which was 34 per 100 was by no means satisfactory. The principal diseases wer malarial fevers, intestinal affections, and influenza, an there were also a large number of cases of pneumonia, whic were to a great extent due to the prevalence of influenza There are six public hospitals—namely, one of 700 beds a Georgetown, one of 150 beds at Berbice (New Amsterdam) one of 53 beds at Suddie, one of 35 beds at Bartica, one o 17 beds at Morawhanna, and one of 30 beds at Arakaka In these institutions there were during the year 14,20 admissions and 1600 deaths of in-patients; there were als 75,356 out-patients treated. At the Lunatic Asylum ther were 149 admissions, 83 discharges, and 85 deaths. Her the principal cause of death was cirrhosis of the liver an kidneys, which proved fatal in 25 instances; 11 deaths wer attributed to cerebral congestion and the same number t tuberculosis. The average number resident daily during th year was 674. At the Leper Asylum there were 277 male and 97 females on April 1st, 1898, and during the ensuing 1 months 78 males and 21 females were admitted, 26 male and 9 females were discharged, and 37 males and 11 female died. The total expenditure of the medical department fo the year 1897-98 was 305,227 dollars.

ANTRAL SUPPURATION.

THE current issue of the Transactions of the Odontologica Society contains an interesting and eminently practical pape by Mr. J. G. Turner on Antral Suppuration. The subject i considered under the headings of Diagnosis and Treatment In dealing with diagnosis the author points out that pu which is pent up in the antrum, although it may cause sever pain, never leads to bulging of the walls, but that in case which have been recorded the bulging was due to denta cysts which had invaded or displaced the antrum and ha subsequently suppurated. In dealing with the value o transillumination as an aid to diagnosis he suggests tha the two sides of the face should be compared a to: (1) illumination of the pupils; (2) appreciation o light by the patient; (3) the light along the lower borde of the orbit; and (4) the light coming through the chink Although he regards transillumination of great value h considers it by no means a certain method of arrivin at a diagnosis, and he lays great stress upon the importance of a preliminary puncture followed by irrigatio in all doubtful cases. In treatment he draws attentio to the importance in chronic cases of making a good openin through the canine fossa, maintaining that it is next to impossible to treat effectively such cases through an opening in th alveolus. Difficulty of treatment arises, in his opinion, from the cellular nature of the upper and inner part of the antrum, especially around the ostium maxillare. These cells are often continued up the inner side of the orbit, and hence there is a danger of the infection spreading to the ethmoidal cells. Thorough treatment of this portion of the antral walls he considers to be most essential and suggests that they should be explored with a probe and regularly swabbed out with pure carbolic acid twice a day.

THE SOPHISTICATION AND CARRIAGE OF MILK.

MILK is at the present time tending to receive some small portion of that attention which its importance as an article of diet for children and invalids merits, and it is to be hoped that the two departmental committees which are now sitting will be able to make such recommendations as will lead to very necessary reform. When, for instance, we read in the current annual reports of Mr. Wynter Blyth, the medical officer of health of Marylebone, that one sample of milk was not only watered and skimmed but had also no less than the enormous amount of 80 grains of borax to the pint, the British Pharmacopœial dose being 5 20 grains, it is clear that at least some regulation of this indiscriminate sophistication of milk is desirable, if only to enable the medical practitioner to have some clear idea of what his patient is taking. There is, by the way, one obvious opportunity for the milk that London drinks to become grossly polluted. Anyone who travels much by train in England must have been struck, especially at night and in the early morning, with the number of enormous metal milk cans which come in and out of the mighty city, and if his curiosity has tempted him to examine these churns more closely he will have noticed that not a few have broken lids which render it impossible to protect the milk from casual or intentional pollution. We believe that certain firms stipulate that the covers of their cans shall be sealed, but we doubt from our own experience whether the precaution is often taken. It would not be difficult to enact regulations rendering the proper sealing of these cans obligatory.

TÆNIA NANA A CAUSE OF CHYLURIA.

IN the Russian Archives of Pathology (tome viii., fasc. 6) Dr. Predtechenski of Moscow reports a case of chyluria which is interesting for several reasons. It is the first case of the kind reported from Russia, though in other parts of Europe cases are occasionally met with in subjects who have not resided in the tropics. Dr. Predtechenski has been able to find some 20 of these cases in medical literature. The cause of tropical cases is generally allowed to be some parasite—filaria sanguinis or distoma hæmatobium. In Europe strongylus gigas has been found and some authors believe that tumours and other pathological conditions which cause stagnation of the chyle and lymph-streams may also produce chyluria. In the Russian case a parasite was detected; at least ova were found in the urine which were diagnosed as those of tænia nana, a minute variety of tapeworm which is tolerably common in Italy but is almost unknown in England, though Dr. Ransom of Nottingham has reported the case of a girl from whose intestinal canal a large number of these parasites were expelled.[1] Dr. Predtechenski's patient was an officer's wife, aged 23 years, who had at times passed turbid or milky urine ever since she was 16 years of age. When seen by him the urine contained, in addition to epithelium, specks or small clots of fibrin, crystals of oxalate of lime, and red and white corpuscles, the last-named having a single spherical nucleus and being in fact small lymphocytes. There were also found some spherical bodies looking like the eggs of some entozoön. They were nearly transparent and under a good immersion lens were seen to possess six hooklets. Their diameter was from 20 to 25 μ and they agreed with the figure of the ova of tænia nana in Mosler and Peiper's work on Animal Parasites. It is suggested that the worm itself may have existed in the kidneys, as another variety—tænia Madagascariensis—is stated to have been found alive in the kidney in a patient suffering from chyluria. The parasite probably occludes the lymphatics and causes them to become distended and finally to rupture, so that the lymph finds its way into the urinary passages. The most efficacious treatment in this case appeared to be gallic acid in 15 grain doses three times a day.

THE CASE OF A NEWSPAPER YELLER.

WE congratulate Mr. Shirley Murphy upon the public spirit which induced him to prosecute a newspaper yeller for obtaining money under false pretences. The extent to which our streets and squares are made hideous by the bawls of these fellows is becoming serious. In many parts of London, and especially at about 10 o'clock in the evening, an hour when the young and the sick are particularly likely to be composed for their night's rest, the streets suddenly resound with raucous bellowings. If anyone, convinced by the violence of the shouting that something really new is to be found in the paper, should become a purchaser, he will assuredly be deceived. The "'orrible slorter," the "magnificent vict'ry," and the "'eavy fightin'" advertised by the yellers are all fictitious to this extent, that the sensational phrases are chosen to describe some small episode in the war that has been published hours, perhaps days, earlier. In the case where Mr. Shirley Murphy very properly put the law in action last week the newspaper tout definitely stated that Ladysmith had been relieved, and charged *3d.* for a *½d.* paper because of the good news of which he was the strident harbinger. Consequently, his conviction was easy to secure. Will a public-spirited individual now try to obtain a conviction on some ground or another, we do not care what, against the more ordinary yeller, who keeps within the letter of truth by being able to show in his paper some sentence, which although describing an ancient event, still justifies to some extent his shouting? The attempt in these cases is really to obtain money under false pretences.

ROENTGEN RAYS IN THE TREATMENT OF LUPUS.

MR. J. F. HALL-EDWARDS contributes a paper to the *Edinburgh Medical Journal* for this month on the Physiological and Therapeutic Action of Roentgen Rays in the Treatment of Lupus. The essentials of the method employed by him are exposure to a highly charged Crookes's tube for a considerable time at short distance. The average duration was 15 minutes and the distance from one to two inches. Three cases are quoted, and though this number is too small to form a basis for generalisation the results recorded are sufficiently obvious and uniform to justify a further trial of the method pursued. 1. A case of lupus vulgaris on the instep. There were five exposures at intervals of from two to three days, except on the last occasion, when nine days intervened. After the fourth exposure sloughing of the patch began and extended for about half an inch round it. The resulting ulcer healed slowly with a sound scar. Two small adjacent patches of lupus which had been protected from the rays by sheet-lead one eighth of an inch thick also became ulcerated and healed in like manner. 2. A case of lupus erythematosus on the arm. This patch was exposed on two successive days. It had sloughed by the twelfth day after the first exposure a week later it was granulating and ultimately healed well.

---

[1] THE LANCET, July 21st, 1888, p. 109.

3. A case of lupus vulgaris in a typically tuberculous patient. A portion of an extensive patch on the front of the right thigh and knee was treated on two occasions. No result was noticed until 18 days later, when the part exposed to the rays was seen to have sloughed away. The ulcer which formed gradually healed with a sound scar. Except in Case 1, where, as already mentioned, lead was used to protect the adjacent skin, the means employed with this object was a solution of gelatin containing iodoform. A coating of this material appears to have answered its intended purpose. In the treatment of these cases a special tube 18 inches long (to avoid sparking over) was used. Mr. Hall-Edwards asserts that one exposure, or at most two exposures, is sufficient and that the number of exposures employed in Case 1 was excessive, the treatment in this instance being necessarily experimental and tentative. Further observation has proved that a latent period of from 14 to 21 days intervenes in any case after the use of the rays before a result can be looked for. He also suggests that a series of exposures at such a distance as to preclude local inflammation might be equally curative. In Mr. Hall-Edwards's opinion the x rays themselves play a very small part, if any, in the process, for, as Nikola Tesla showed, they easily penetrate an aluminium shield which suffices to prevent burning of the skin. He attributes the beneficially irritant and ulcerative effects to electrical action.

PREMATURE BURIAL.

FROM time to time there come to the fore most ghastly stories of cases of premature interment. Only recently two instances have occurred in Italy. One of these was published in the letter from our Rome correspondent which appeared in our issue of Feb. 24th and a second case is mentioned in the letter from him which will be found in another column. The first case was accompanied by the additional horror that the victim is said to have given birth to a child in a coffin. This at least was the report of the judicial authorities who added that both mother and child had died from suffocation. While it is impossible to prove that the child was not born alive, we think it exceedingly unlikely. It was minus both arms, which had apparently been pulled off by the efforts of those who had attended the mother in her confinement to extract it. That a child should be born alive more than 24 hours after receiving such injuries is, to say the least, very doubtful. Neither does the fact of the fœtus being extruded prove absolutely that the mother must have been alive when buried; this at least is the opinion that has been recorded by some observers. In the case which appears at p. 661 there seems no doubt that the man really was alive when placed in the coffin. There appears to be no information as to whether the death was certified by a medical man as the result of his personal investigation.

MORE OYSTER-BORNE ENTERIC FEVER.

FROM the West of England comes a story of an outbreak of enteric fever in which oysters seem to have played a very conspicuous part. Two servants, a footman and a maidservant, employed at a country seat in Cornwall were attacked by enteric fever soon after consuming certain oysters, and the maidservant succumbed to the malady. At the same house was a shooting party, and two of the guests left on Nov. 11th after having during their stay eaten freely of oysters. These gentlemen were taken ill with enteric fever at their respective homes, the one on Nov. 24th and the other on Nov. 26th. Moreover, a lady guest left this house on Nov. 28th for Ireland taking with her a supply of oysters, some of which she gave to her brother on her arrival. On Dec. 17th this brother developed enteric fever. All the oysters here in question were procured from the same source, and the circumstances remind us of the outbreak at the Connecticut Wesleyan College, in that the oysters were originally procured from a source relatively free from pollution, but were laid down prior to sale for consumption on what appears to be a highly polluted foreshore. The suspected oysters were laid down in the Penryn river off the village of Flushing and opposite to the town of Falmouth. This river is, we learn from the Local Government Board report on Oyster Culture, only one and a half miles in length, and at the head of it the town of Penryn with a population of 3256 pours its sewage. In addition to this there are on the foreshore of Flushing, as also on the opposite side of the river, numerous drains discharging. The oyster layings in the Penryn river must, Dr. Bulstrode states in his report, be regarded as occupying a dangerous position. It is a serious reflection on this state of affairs to read in the report of the meeting of the East Kerrier District Council, at which this matter was discussed, and that various proposals were made for dealing with the danger, but that "it was thought that the authority had no power, and nothing was done."

THE ROYAL NAVY MEDICAL SERVICE.

WE are glad to notice that Sir Walter Foster spoke in terms of commendation of the changes which the First Lord of the Admiralty proposes to make in the Royal Navy Medical Service, for these changes are unquestionably of a highly desirable nature. They are really needed and they will have the effect of greatly increasing the efficiency of the service. It will be remembered that when the report of the committee on the subject was published some time ago it met with our cordial support. We concur with Sir Walter Foster in thinking that the reforms introduced by Mr. Goschen form an enlightened departure. They will afford satisfaction to the medical profession as a whole and will encourage its younger members to enter upon a career of great usefulness. There is surely no need to point out how essential it is that medical officers, separated by their calling and duties from centres of scientific activity, should have every opportunity of keeping abreast with the progress of medicine and surgery and the newest methods of treatment. It is obviously a duty they owe to those committed to their charge. There are many doors to post-graduate study open to medical officers of the services nowadays and we trust that every practicable facility will be extended to them to enter.

THE VALUE OF TECHNICAL CERTIFICATES.

THE movement of the proverbial straw indicates the direction of the wind, and the case tried recently between Sir Philip Magnus and the Plumbers Company indicates much more than the falling out of faithful friends. Sir Philip Magnus sued to be re-instated in his position upon the Court of the Company, from which the company had for a time excluded him, he being a member of the Court, and judgment was given in his favour. Any quarrel between Sir Philip Magnus and the Plumbers Company upon private grounds would not come within the scope of our consideration, but it seems to us that in this dispute questions of considerable, if indirect, influence upon public health were involved. From correspondence that passed some two years ago between Sir Philip Magnus and the Plumbers Company, upon which we commented in THE LANCET of October 2nd, 1897 (p. 872), it appeared that the real matter at issue between the parties was as follows. The Plumbers Company, or rather the Examining Board of the Company, composed of master and operative plumbers selected to represent the plumbing trade, refused to register as plumbers the certificated pupils of the City and Guilds of London Institute, in which Sir Philip Magnus holds the post of superintendent of technological examinations, unless the candidate first passed the practical tests set by the Examining Board of the Plumbers Company. The Plumbers Company seem to have had, as they possibly still have, grave doubts as to the practical nature of the work done by the pupils of the Institute. Their object is to avoid the registration of any but men who intend to follow the craft of plumbing for a livelihood and who therefore must have a thorough working knowledge of it in every detail. We sympathise with this object heartily.

AT the forthcoming dinner to be given by the Royal Medical Society at Edinburgh on March 6th the guest of the evening, Mr. Victor Horsley, will speak on the subject of "The Medical Corporations," instead of proposing the usual toast. A further indication of the newly awakened interest in the position of medical men is evidenced by a movement now in progress in the eastern and midland counties to arrange a gathering of the profession in the spring to hear the situation discussed by the Direct Representatives on the General Medical Council.

THE annual dinner of the Irish Medical Schools' and Graduates' Association will take place on St. Patrick's Day, Saturday, March 17th, at the Hotel Cecil, at 7 15 P.M. The honorary secretary, to whom all communications should be made, is Mr. P. J. Freyer, 46, Harley-street.

A TELEGRAM from the Governor of Mauritius, Sir Charles Bruce, received at the Colonial Office on Feb. 23rd, states that during the week ending Feb. 22nd eight fresh cases of plague occurred with four deaths. Six cases have also been reported from Aden with one death.

IT is announced that Dr. Sydney Ringer, F.R.S., and Mr. Christopher Heath, the senior physician and surgeon respectively to University College Hospital, are about to retire under the ordinary rules from service upon the active staff.

MR. THOMAS SCATTERGOOD, of Park-square, Leeds, Lecturer on Forensic Medicine at the Yorkshire College and Dean of the Medical Department, died on Feb. 22nd.

THE Admiralty have sanctioned a proposal to provide new naval sick quarters, with a dispensary, at Sheerness, at an estimated cost of £12,000

THE second reading of the Bill for the Registration of Midwives which was down for Wednesday, Feb. 28th, was not reached.

NURSES' HOME AT BATH.—At the meeting of the Bath Board of Guardians held on Feb. 21st it was decided to erect a nurses' home to give accommodation for 20 nurses. The cost of building is estimated at about £2000.

ROYAL DEVON AND EXETER HOSPITAL.—The annual meeting of this institution was held on Feb. 22nd under the presidency of Colonel Lucas. The medical report stated that 1322 in-patients had been admitted, against 1343 in 1898. The out-patients numbered 4303, against 3850 in the preceding year. 75 patients had been sent to the Ockenden Convalescent Home in connexion with the hospital. The average daily number of in-patients was 145. The financial statement showed that the income from all sources amounted to £13,698, the ordinary expenditure was £8460, and the extraordinary expenditure was £3677, making a total of £12,137.

THE WAR IN SOUTH AFRICA.

THE splendid news has come at last. Ladysmith is relieved and General Cronje has surrendered with all his force.

The brief telegram from Lord Roberts intimating the latter piece of intelligence to Her Majesty's Government was not without a touch of dry humour. Cronje is our prisoner and the unconditional surrender of his army by the irony of fate and a remarkable coincidence occurs on the anniversary of the Majuba Hill disaster, after which reverse to our arms Great Britain gave an example of magnanimity never likely, we imagine, to be repeated in our experience, for the source of the present troubles may be traced to the root which was then planted. Cronje's surrender was a foregone conclusion having regard to the circumstances in which he found himself and the hopeless straits to which his force had been reduced, but this does not render the news any less welcome or important. The result has been brought about by brilliant strategy and admirable tactics on the part of the British leaders, and Lord Roberts has exercised very proper humanity and a wise discretion in delaying the further and complete destruction of a force which was within his grasp at any moment that he liked to crush it. The end is not yet, perhaps not near, but when it comes it will have been purchased with the blood of some of the noblest and bravest of our race and by the outpouring of treasure without stint under the firm conviction on the part of the British Empire that the cause was one of right, justice, and humanity. The empire is of one mind and determined to achieve its purpose. The fruits of its sacrifice and labours will one day be recognised and reaped by all the world, including those who have hitherto been forward to scoff at our arms, revile our motives, and misrepresent or belittle our labours and achievements on the battle-fields of South Africa.

We have now to await with patience the receipt of detailed news from General Buller, whose force has fought its way laboriously and step by step through all those topographical and natural obstacles which lend themselves so powerfully to the Boer system of warfare The hardest task in the present war fell to the lot of General Buller, and that he has reached his goal proves both his resourcefulness and the indomitable pluck of his officers and men. He was resolved to win through and the forces under his command had entire confidence in his military capacity and ability to conduct them to the successful accomplishment of the relief of Ladysmith. When those who laid down cheerfully their lives under his command and who had the best opportunities for estimating his difficulties and his power to overcome them were content to wait his time, we may be sure that no earlier relief of the beleaguered city was humanly possible. We do not yet know whether the Ladysmith garrison under Sir George White were able to contribute largely to effect their own relief. The monotonous life and diet during the siege, the want of stores for men and horses, and the large number of sick present in Ladysmith must have handicapped their efforts, but we may be sure that they made every attempt to aid the relieving army at the opportune moment. It is a noteworthy fact that the soldiers who are fighting our battles in South Africa never seem to have any misgiving as regards their leaders; on the contrary, they are in excellent fettle and animated with a firm belief in ultimate success; and they never fought better than they have been doing in South Africa. It is certain that no other country could have accomplished in the matter of organisation what England has already done in this war; and after every allowance has been made to our discredit for miscalculations and mistakes it is very questionable whether the army of any other nation would have done better, if as well, in actual fighting under all the adverse circumstances. We await with anxiety full information concerning the condition of the relieved garrison, but our anxiety is tempered by the knowledge that all possible provision has already been made in Natal to receive the sick along the lines of communication and to transmit them with every comfort to the base.

The medical service is continuing to do excellent work in all directions and of the most varied nature. The officers country for the fertility of resource, zeal, and ability which they have displayed and for the energy with which they have worked throughout. All who have had opportunities of ascertaining the facts add their testimony to that of Sir William Mac Cormac and others in respect of the medical arrangements, and testify to the promptitude and readiness with which the War Office have complied with every wish and responded to all suggestions in regard to the conveyance of surgical instruments, specially prepared dressings, and other appliances necessary for the treatment of urgent cases requiring immediate operations.

Preparations have been made at Durban and at Pietermaritzburg to celebrate the relief of Ladysmith which was expected hourly, while Sir William Mac Cormac, in his notes this week speaks of the excellent arrangements that have been made at No. 4 General Hospital at Mooi river. Mr. Treves has expressed his complete satisfaction with the management of the hospitals at Pietermaritzburg and other centres. The field hospital arrangements, he said, were as perfect as they could be, and he records a strong testimony to the devotedness of the stretcher-bearers. He added that, in his experience, the Boers had treated our wounded very kindly. The generous efforts of the colonists on behalf of the wounded also elicited from him a word of grateful recognition. Lord Roberts stated in regard to the hospital at Kimberley that Lord Methuen's account of the admirable manner in which the Kimberley hospital was managed had made him desire to send some of his sick and wounded there.

Royal Visits to the Wounded.

Within the last few days the Royal Victoria Hospital, Netley, has received large batches of sick and wounded from South Africa. The *Kildonan Castle* arrived at Southampton on Feb. 23rd and as the vessel reached the Southampton quay news of the relief of Kimberley was shouted to those on board and received with ringing cheers. The vessel brought 178 men from the front, 53 of whom had been wounded. Captain Lugard of the Indian Staff Corps was among the invalids. Most of the wounded men had received their injuries either at Colesberg or at Magersfontein. The patients were nearly all convalescent, thanks to the skill of Fleet-Surgeon Saunders, R.N., and of Dr. Wilburn, the medical officer of the vessel, who divided the work between them during the voyage. All the invalids were speedily attended to and were transferred into the hospital train and reached Netley early in the afternoon.

The Princess of Wales and her Hospital Ship.

On Feb. 25th the hospital ship, *Princess of Wales*, which left the Cape on Feb. 1st, came into Southampton Water. She brought home 174 men under the command of Major A. Hickman Morgan, D.S.O., late Surgeon-Major A.M.S., the principal medical officer, who on arrival was able to give a very favourable account of the patients. Nearly all of the men had been wounded, but so favourable had the cases been that only one cot case was landed at Southampton. No operations had been performed on board, but a number of bullets had been localised by the x ray apparatus presented to the ship by the Duke of Newcastle. The majority of the men had been wounded at Magersfontein and the Modder river, the regiments represented being the Coldstream Guards, the Argyll and Sutherland Highlanders, the Highland Light Infantry, the Royal Engineers, the Royal Artillery, the Scotch and Dublin Fusiliers, and the Grenadier Guards. Lord and Lady Wantage were awaiting the steamer's arrival accompanied by Major W. G. Macpherson, R.A.M.C., who did such excellent work in connexion with the fitting out of the vessel. Lord Wantage expressed his gratification at the facts that no death had occurred during the voyage and that the patients had made such excellent progress on the road to recovery. The wounded were not landed on the day of arrival as the Princess of Wales had intimated her intention of visiting her hospital ship—a visit which was looked forward to by the men with the keenest interest. The next day (Monday) opened with heavy rain and fog, which continued until nearly 10 o'clock when the sun burst forth brilliantly through the clouds, rapidly dispelling the vapour, and beautiful weather prevailed long before the arrival of the royal train. Carrying out the instructions received from Marlborough House, no one was allowed to enter the wharf where the royal party alighted. The Prince and Princess of Wales, accompanied by the Duke of York, left Waterloo station at 9.30 A.M., and travelling over the London and South-Western Railway reached the docks at 11.20. Their Royal Highnesses were attended by Colonel Sir Nigel Kingscote, Lady Emily Kingscote, Miss Knollys, and Major the Hon. Derek Keppel, and were accompanied by the Hon. Sydney Holland, representing the Red Cross Society. On the platform to receive the royal party were stationed Lieutenant-General Sir Baker Russell, commanding the Southern Division, and his staff, and Captain G. White, R.N. The royal visitors, accompanied by their suite, proceeded by the gangway, which was beautifully decorated, on board of the vessel and were duly received by the captain and officers of the vessel and by Major Hickman Morgan and Major Macpherson, with each of whom the Princess shook hands. Her Royal Highness graciously accepted a beautiful bouquet of lilies of the valley, attached to which were red and white streamers. The Princess visited each patient, their cases being explained to her by Major Hickman Morgan. She spoke in most kindly terms to the men, who were much touched by her gracious manner. Her Royal Highness inquired at some length as to the manner in which the vessel had performed her mission during the voyage, one and all of the men declaring that they had been most comfortable and that every possible requirement was at hand. Most of the patients were sufficiently recovered to be able to stand at attention by the side of their cots, but noticing that in many cases they looked pale and weakly Her Royal Highness promptly directed that all who cared to do so should be seated, an act of thoughtful kindness which went straight to the hearts of the soldiers. Early in the visit Major Hickman Morgan drew attention to a man of the Gordon Highlanders who had been shot in the top of the head while lying in front of the trenches at Magersfontein. The bullet had destroyed the left eye in its course and had emerged at the chin. A man of the Royal Artillery who was shot in the leg was able to produce for inspection the Mauser bullet which had been extracted. Among the patients was a man who had been wounded in the head and whose case has been described by Sir William Mac Cormac as one of the most extraordinary he had ever heard of. Major Hickman Morgan, while showing the Princess a Mauser bullet which he had extracted, stated that the bullet was perhaps the most merciful ever used in warfare. A few of the patients had been suffering from typhoid fever and dysentery, and one of the most serious of these was berthed in the Maud Ward, named after the Princess's youngest daughter. At the end of the visit those men who were sufficiently well were assembled on the deck and they cheered the royal visitors when leaving. The arrival of the *Kildonan Castle* and the hospital ship the *Princess of Wales* has not only again filled up the wards of the Royal Victoria Hospital at Netley, from which a steady stream of men have been passed to convalescent homes and to sick furlough, but has also been the means of bringing Netley the honour of two Royal visits on successive days.

The Prince and Princess of Wales and the Duke of York at the Royal Victoria Hospital, Netley.

On leaving the *Princess of Wales* hospital ship on Monday last the party, accompanied by the military staff of the Southern Division, were conveyed by a special train to Netley. The train steamed into Netley station at 1.20 P.M. when carriages were in waiting to convey the visitors to the officers' mess of the Royal Army Medical Corps where they were received by Colonel Charlton, the principal medical officer at Netley, and his staff. After lunching with Colonel Charlton and the officers of the Royal Army Medical Corps in their fine mess-room, the whole party proceeded to the hospital, where Miss Norman, the lady superintendent of nurses, was introduced. They were then taken through the wards and corridors, in which were drawn up all the patients who were sufficiently convalescent. All the wounded in bed were visited in turn and for each the Prince and Princess of Wales had a kindly word. The visit lasted for about an hour and a half, and after it the royal party returned to London, arriving at Waterloo at 6 o'clock.

The Queen at the Royal Victoria Hospital, Netley.

The visit of their Royal Highnesses the Prince and Princess of Wales, accompanied by the Duke of York, which gave such sincere satisfaction both to the sick and wounded from the front and to those on whom devolves their care while restoration to health is being accomplished, was followed 24 hours later by a visit from Her Most Gracious Majesty the

Queen, who as age advances does not permit those qualities to diminish which have ever marked her out among sovereigns —the qualities of sympathy with the afflicted and pity for the suffering. These qualities, often before displayed during and after the wars in which her armies have been engaged, were again exemplified by her visit to the Royal Victoria Hospital on Tuesday afternoon last, Feb 27th, when she made a tour of the grand base hospital of the South African army and learned from the men's own lips something of the dangers through which they had passed. The effect of such a visit is truly gratifying to the whole army and will never fade from the memories of the men who have suffered in Great Britain's cause and who the more thoroughly appreciate the Queen's kindness and thoughtfulness from a knowledge of the fatigue which must be inseparable from such a visit at Her Majesty's time of life.

Before her arrival letters were received by the principal medical officer in which Her Majesty expressed her wish that only the officers and nurses who were engaged in the treatment of the patients in the various wards should accompany her to the different divisions of the hospital— a wish which was of course carefully attended to. The royal party travelled from Windsor Castle *viâ* Basingstoke and Fareham, arriving at the Netley railway station at 1.30 P.M., where Her Majesty was met by Lieutenant-General Sir Baker Russell, commanding the Southern Division, and his staff; Colonel Napier, his chief staff officer; Major Kinloch of the 60th Rifles, acting aide-de-camp; and Major Creagh, the assistant adjutant-general at Netley. Proceeding from the station in carriages, through part of Netley village, Her Majesty, who was accompanied by H R.H. the Princess Beatrice and the Princess Victoria of Schleswig-Holstein and attended by her equerries, Sir John M'Neill, V.C., and Captain Ponsonby, and by Lady Ampthill and Miss Moore, arrived at the west door of the hospital at 1 45 P.M. Here she was received by a guard of honour of the 4th Battalion of the Lincoln Regiment who were drawn up in front of the portico, under which Captain Stevens, R E., had erected a platform to facilitate Her Majesty's passage from her carriage to the lower corridor of the hospital. The morning, like that of Monday, had opened with much rain, a damp mist hanging over Southampton Water, but during the morning the weather much improved and the sun shone during Her Majesty's short drive. Greeted by the strains of the National Anthem Her Majesty walked, leaning with her left arm on an Indian attendant, up the platform, where she was received by Colonel Charlton, principal medical officer of the hospital, and was presented with a lovely bouquet by Mrs. Charlton. On reaching the door of the hospital the Queen entered her wheeled chair and the military staff of the hospital were presented to her by Colonel Charlton. The officers who had this honour were Colonel K. MacLeod, Lieutenant Colonel W. E. Webb, Lieutenant-Colonel Hughes, Lieutenant Colonel Chester, Major W. Dick, Captain Stevens, R.E., and Lieutenant Prentis, and the chaplains of the hospital. Accompanied by Colonel Charlton Her Majesty was wheeled to the lift, in which she was conveyed to the surgical division of the hospital. There she made a careful inspection of the wards, being shown many of the scars made by the Boer bullets and presenting flowers to the men. Her Majesty remarked on the proportion of Highlanders found among the wounded and was informed that a large number of them had suffered at Magersfontein. She remarked to Colonel Charlton on the good news which she had received in the early morning from Lord Roberts and inquired if the men had been informed of it. Being answered in the negative, she requested the principal medical officer at once to announce it, which he did in the terms of Lord Roberts's telegram giving out that General Cronje had unconditionally surrendered to Lord Roberts and upon the anniversary of the Majuba Hill reverse. To one man of the Connaught Rangers Her Majesty remarked that the Irish regiments had done very well during the war, and to another she said, "You have had a hard and severe time." Many of the men to whom the Queen presented flowers were so much affected that they were unable to answer her questions or to express their thanks. From the surgical division Her Majesty passed to the medical division where the cases were explained by Colonel Webb. The whole tour of the hospital occupied two hours, and at its termination, at 3 45, Her Majesty and suite left for Windsor.

(NOTES FROM SIR WILLIAM MACCORMAC.)

(Continued from p [illegible]02.)

I and my secretary arrived at Durban on Jan. 27th. The news there was of a disquieting nature, a private report having found credence to the effect that the whole of Buller's army had recrossed the Tugela, having been unable to hold the kopjes they had gained during the previous seven days' fighting. I determined, however, to push on to No. 4 General Hospital at Mooi river at once in the hope that these reports might prove to be untrue and that I might be near at hand for the purpose of participating in the expected relief of Ladysmith. I arrived at Mooi river at 2 A.M. on the 28th and during that day we heard news which confirmed the Durban rumours. At present, therefore, nobody can say when a new advance may be made, and so I determined to remain at this hospital for the present and do what work may come to hand here During the three days after my arrival the two hospital trains made ten journeys, carrying the wounded between them from Frere to Estcourt, to this hospital, to Pietermaritzburg, and to the hospital ships at Durban. Each train can convey 69 patients lying down and a great many more patients sitting up. During these ten journeys they brought down close upon 1100 cases and there are, at the date of writing this, still about 250 to bring

The situation of affairs as regards the medical organisation in this locality at present is as follows. The field hospitals with the brigades in the fighting line were situated about nine miles from the Tugela river on the further side. The wounded were carried by stretchers and ambulances back across the river to the Stationary Field Hospital, situated on this side of the Tugela, 22 miles up the stream from Frere. This hospital (which I described in my account of the battle of Colenso) has become enlarged from its original size of 150 beds to one of 400 beds. The wounded have been treated and operated upon in this hospital and as they become fit for transport have at once been conveyed by hand stretchers and waggons across the 22 miles of plain to Frere station. The stretchers are carried by volunteer ambulance bearers After this excessively tedious journey the patients are at once loaded, on arrival, into the hospital trains, the excess being temporarily accommodated in a field hospital of 100 beds at Frere. The hospital is under the command of Major Kirkpatrick, R.A.M.C., and the hospital at Frere is commanded by Major Daly, R A.M.C. Both of these hospitals have civilian surgeons attached to them for duty under the officers of the Royal Army Medical Corps.

The weather at present is very rainy and the journeys of some of the wounded have been carried on under great difficulties. As the future movements, however, of the army are at present very uncertain the transport of the wounded must of necessity be carried on so as to make room for possible fresh contingencies. The hospital trains are well supplied with luxuries and the wounded are at once fed with comforting soup and drinks. On their arrival at this station (Mooi river) those of the wounded who are destined to remain at this hospital are conveyed in a most comfortable and easy manner by means of the MacCormac-Brooke wheeled stretchers to the hospital on a hill about half a mile from the station. This hospital, No. 4 General Field Hospital—No. 1, No 2, and No. 3 being at the Cape side—has been established in this locality since my last visit, which was in December. It is under the command of Colonel Clery, R.A.M.C, principal medical officer of the lines of communications, his staff consisting of Major Lucas, R A.M.C (secretary and registrar), Major Hackett, R.A.M.C, and Major Fryer, with a lieutenant, a quartermaster, and ten civilian surgeons. There are also eight nurses of the Army Nursing Service attached.

The history of this hospital may be summed up by briefly detailing the diary of the days following its arrival here. The Mooi river is a rapidly flowing stream which at this spot is about 50 yards in width. The railway station is on its left bank and the country runs away from its right bank in large undulating grass downs resembling Salisbury Plain. About 50 yards from the railway station there is a small railway hotel, about a quarter of a mile from the left river bank, which is used as a hospital for officers (see plan).

Jan. 6th —Arrived at Mooi river and surveyed the ground for No. 4 Hospital on the right bank of the river in the evening.

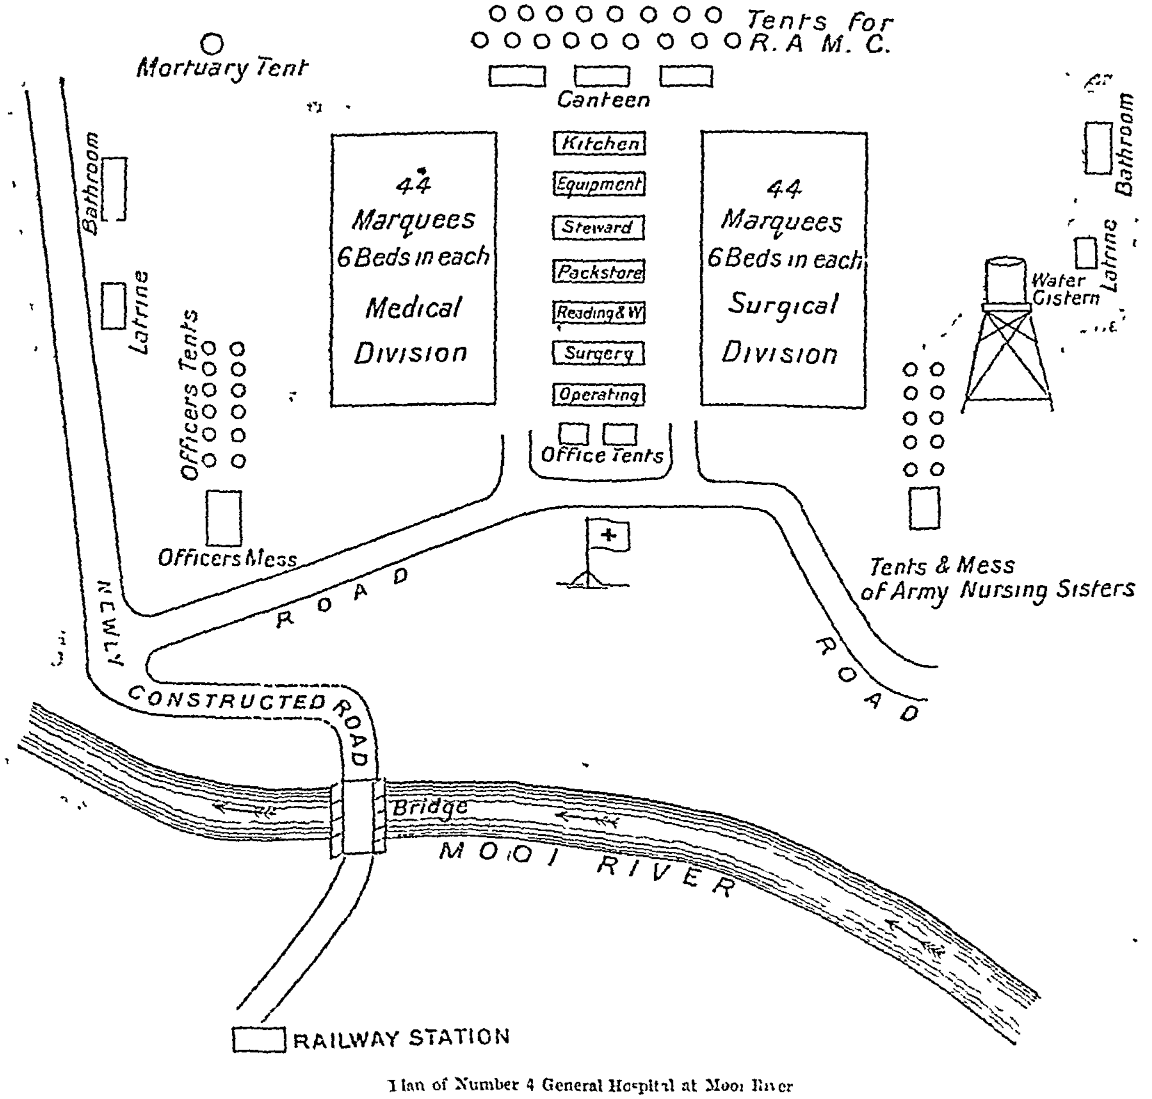
Jan. 7th —Pegged out the ground for marquees and bell-tents and unloaded part of the hospital equipment from the train. Only five waggons could be used for conveying equipment across the river to the site chosen on account of the fear of blocking the narrow fording-place in the river.

Jan 8th.—Continued the unloading and erection of the tents.

Jan 9th and 10th —Bad weather having set in the river became so swollen that the ford was impassable and it became necessary to send the waggons round by a devious route of four miles. The strength of the rank and file, which had been two warrant officers and 143 non-commissioned officers and men on arrival, was diminished by the withdrawal to Spearman's Camp of 50 non-commissioned officers and men. This camp was also supplied with one officer of the Royal Army Medical Corps and six civil surgeons, leaving a very diminished staff to carry on the work of organisation.

Jan. 11th.—Took over the Railway Hotel and equipped bedrooms for the accommodation of 30 officers. 48 marquees were equipped and got ready this day and the first sick party, consisting of 300 patients, arrived.

The hospital at present is situated upon the gentle slope of a grassy hill. It consists of 88 marquees for the accommodation of sick and wounded. Each marquee contains six beds. The floors are covered with tarpaulin. The arrangement of the marquees is most excellent, the hospital being divided into two halves, medical and surgical, with a space between. In this space are situated the administrative tents and buildings. These buildings are of galvanised iron and they have been erected very rapidly by the Royal Engineers. They are not all yet completed, but several of them are in working order, notably the kitchen, which is a commodious structure fitted with water taps and boiling cisterns for sterilising the drinking-water. The surgery, the operating room and the x-ray room, the reading- and writing-room, the pack store, the steward's store, and the equipment store, which at present occupy marquees, will be provided for by buildings. On each flank of the hospital there is situated a bath-room containing four large baths and also a latrine provided with buckets. The water is laid on by pipes in the bath-rooms. A large water cistern has been erected upon a 50-feet platform, from which the water is carried in underground pipes by gravitation. The supply of water to the cistern is pumped up from the river by a pumping apparatus on its bank. The drinking water is filtered through sand and cloth in a special cistern. It is conveyed by pipes to the kitchen where it is boiled and afterwards passed through a Berkefeld filter. It is then aerated through charcoal filters and distributed in special drinking vessels to the patients. An operating room is at present being constructed; it will be of ample dimensions, so that two operating tables can be conveniently used at the same time. One corner of this building is being cut off to be converted into the x-ray and photographic room. A general idea of the arrangements may be obtained from the following plan:—



Plan of Number 4 General Hospital at Mooi River

I append notes of several very interesting cases which are at present under treatment in No. 4 General Hospital, the patients having been conveyed there from the various field hospitals at the front. These notes were taken on the occasion of my inspection of the hospital on Jan. 31st and represent the condition of the wounded which was noted on that date.

CASE 1. *Wound of the head and the neck.*—Private —— was wounded on Jan. 21st at a range of 800 yards. The entrance wound was precisely through the centre and middle line of the nose immediately beneath the nasal suture. The wound of exit was behind on a level with the sixth cervical spine and about an inch to the right, the bullet having passed in its course through the base of the uvula close to its junction with the soft palate. The symptoms were bleeding from the mouth and epistaxis for about a week and some difficulty in swallowing. There are no other symptoms at present except headache and some dilatation of the left pupil. The wounds healed and on the 31st the patient was apparently otherwise perfectly well.

CASE 2. *Wound of the neck and the lung.*—Private —— was wounded on Jan. 24th from an unknown distance. The entrance wound was at the anterior margin of the right trapezius two inches above the centre of the right clavicle. The wound of exit was on the left side in the tenth intercostal space two and a half inches from the middle line. The symptoms were hæmoptysis for two days after the injury. He has felt perfectly well ever since the wounds healed.

CASE 3 *Wound of the lungs.*—Private —— was wounded on Jan. 20th from a distance of about 700 yards. The entrance wound was at the upper part of the left posterior axillary fold. The wound of exit was at the ninth intercostal space on the right side, five inches from the middle line of the back. There was slight hæmoptysis from the receipt of the injury up to the 31st. The temperature was normal and there was slight dyspnœa. The patient was progressing favourably and the wounds had healed.

CASE 4. *Shell wound of the chest wall, involving the lung and pleural cavity.*—Private —— was wounded on Jan. 23rd from an unknown distance by a portion of a shell. There is at present a large shell wound, about seven inches long by three inches in width, running from the right nipple almost transversely backwards, occupying the region of the fourth, fifth, and sixth ribs, which have in part been carried away, leaving a large chasm. The pleural cavity has been freely opened, the lung being exposed The patient states that he lay in a trench on the field from 2.30 P.M. until 5 P.M. before he could be attended to. He was carried to the hospital at 12.30 that night. On the 31st there was no cough or dyspnœa and the temperature was normal. The man states that he has suffered very little indeed from this extensive injury at any time and that he had no shortness of breath or spitting of blood and no evidence of any shock could be obtained. In the bottom of the large open wound the lung is plainly visible and the parts are beginning to granulate. The man looks extremely well and says he has nothing whatever to complain of.

CASE 5. *Wound of the lung.*—Private —— was wounded on Jan. 20th from a distance of 600 yards. The entrance wound was at the sixth interspace on the right side, five inches from the median line. The wound is of the small characteristic variety and is still unhealed. It is not known where the bullet is lodged. He will be x-rayed. There were no symptoms beyond slight hæmoptysis and on the 31st he was convalescent.

CASE 6. *Wound of the lungs.*—Private —— was wounded on Jan. 20th at a range of 1600 yards. The entrance wound was immediately over the second left rib one and a half inches external to the margin of the sternum. The wound of exit was through the eighth right interspace one and a half inches below, and slightly internal to, the inferior angle of the scapula The symptoms were slight hæmoptysis for two days with slight cough and dyspnœa. On the 31st the man's condition was good and the wounds were healed.

CASE 7. *Wound of the hand, the lung, and the abdomen.*—Private —— was wounded on Jan. 24th from an unknown distance. The entrance wound was of the characteristic circular type and was situated three and a half inches vertically below the right nipple, the bullet having first traversed the second right metacarpal bone. The wound of exit was slightly to the left of the second lumbar spine. The symptoms were *nil* and the wounds had scabbed over. On the 31st the man was quite convalescent and had nothing apparently the matter with him. The entrance wound in the finger is as clean cut a circle as that in the chest.

CASE 8. *Wound of the lungs.*—Private —— was wounded on Jan. 21st from an unknown range. The entrance wound was one and a half inches above the clavicle at the outer border of the sterno mastoid on the right side. The wound of exit was one inch above the posterior axillary fold on the left side. There was also an exceedingly oblique fracture of the left clavicle. This fracture was not in the bullet track, but the man persisted in ascribing the fracture to the bullet. Its obliquity contradicts his opinion. He denies a fall or any other accidental violence. The symptoms were *nil* beyond the pain of the fractured clavicle.

CASE 9. *Wound involving the lung and the abdomen.*—Private —— was wounded on Jan. 20th at a range of about 1000 yards whilst lying in a prone position. The entrance wound was on the anterior surface of the right shoulder two inches below the acromion. The bullet was cut out about two inches below the centre of the fold of the right buttock, having lodged immediately beneath the skin. It had thus raked, as it were, the whole length of the man's trunk fore and aft. There was hæmoptysis for three days after the receipt of the wound On the 31st the patient was convalescent, the wounds having healed. No further symptoms of any kind occurred.

CASE 10. *Wound of the abdomen.*—Captain ——, R.A.M C., was wounded on Jan 23rd near Colenso at a distance of 100 yards whilst he was bending over in the act of dressing a wounded man. The wound of entrance was through the right rectus abdominis muscle, one inch below the costal margin and one and a half inches from the median line. The wound of exit was one inch above and one inch behind the centre of the right iliac crest. The symptoms were *nil* throughout, although it was difficult to suppose that the ascending colon escaped perforation. This officer watched himself carefully for symptoms which he believed must inevitably arise. He knew where the entrance wound was almost directly, but did not localise the position of the exit wound for two hours afterwards. He tried to finish the dressing of the wounded man but became giddy and had to lie down. He then remained perfectly still on his back for 12 hours, suffering much from the constrained position but nothing from his wound, and refused to take some water offered to him by the Boers. Two other men close by, who were also shot through the abdomen, did drink, although strongly advised by him not to do so, and soon began to suffer very much, one vomiting constantly. The captain had only eaten a little porridge for breakfast ten hours before and took nothing by the mouth for 48 hours afterwards. On the 31st he was convalescent and he had had no abdominal symptoms throughout.

CASE 11. *Wound of the pelvis and the rectum.*—Captain —— was wounded on Jan. 23rd at a range of 500 yards. The entrance wound was an inch below and an inch behind the tip of the right trochanter major. The wound of exit was half an inch vertically above the tip of the left trochanter major. There were immediate and copious bleedings from the rectum and for several hours following; subsequently there was a thin, bloody discharge with tenesmus. On the 31st the external wounds were healed. There was considerable ecchymosis present in and around the anus and buttocks. There was no evidence of any local inflammatory disturbance. This officer said he felt as if he had been again operated on for piles. On the 31st he was quite convalescent. Without doubt the bullet traversed the rectum

CASE 12. *Wound of the pelvis and the thigh.*—Private —— was wounded on Jan. 20th at a range of 700 yards. He was lying prone when hit. The entrance wound was three inches behind the anterior superior iliac spine on the left side and an inch below the crest of the ilium The wound of exit was at the perineal margin, two inches behind the scrotum on the left side The bullet entered again at the junction of the upper and middle thirds of the right thigh, a little posterior to the adductor longus. It emerged finally near the upper end of the outer boundary of the right popliteal space. There were no symptoms and on the 31st he was convalescent. The position he lay in probably saved the testicles from injury.

CASE 13. *Wound of the thigh and the femoral artery.*—Private —— was wounded at Spion Kop on Jan. 21st at a range of 1100 yards. The entrance wound was immediately behind the tensor vaginæ femoris four inches above the left knee. The exit wound was on a little lower level on the inner side. Pulsation could be felt in the posterior tibial artery and in the dorsalis pedis artery. The bullet passed between the bone and the femoral artery, making a large wound in the artery on its anterior aspect. He was admitted to hospital on the 26th and damage to the femoral artery was diagnosed as there was a pulsating swelling with a loud bruit over the lower part of Hunter's canal. On the 28th an incision was made over the lower portion of Hunter's canal and the wound of the artery was found to be just above the opening in the adductor magnus. There was a very small amount of extravasation of blood present. The artery was ligatured above and below the wound and divided between. The anastomotica magna was also ligatured. On the 31st the patient was progressing satisfactorily and the collateral circulation was fully established. The small amount of extravasation from a large wound in a large artery was noteworthy.

CASE 14. *Wound of the thigh, the leg, and the tibial nerve.*—Major —— was wounded on Jan. 24th at Spion Kop. The entrance wound was immediately behind the insertion of the right biceps femoris tendon after grooving the skin of the thigh for six inches, leaving a narrow long black scabbed groove. The wound of exit was immediately behind the inner border of the tibia three inches above the internal malleolus. The anterior tibial nerve was injured, drop-foot and anæsthesia in the area of the nerve distribution being present.

CASE 15. *Wound of the knee.*—Private —— was wounded on Jan. 21st from an unknown distance. The entrance wound was beneath the outer margin of the left patella about the junction of the upper and the middle thirds of the bone. The wound of exit was just anterior and internal to the semitendinosus tendon opposite the joint line. The limb was in a splint but was now capable of flexion at the knee. There was some effusion into the joint, but no tenderness or rise of temperature. The wounds were healed on Jan. 31st and the man will doubtless have a perfectly useful joint and limb.

CASE 16. *Wound of the axillary artery and the musculo-spiral nerve.*—Private —— was wounded on Jan. 15th at a range of 600 yards. The entrance wound was half an inch vertically above the reflection of the anterior axillary fold from the chest wall on the left side. The exit wound was at the reflection of the skin from the thorax to the arm behind on the same side. On his entry into the hospital the patient was suffering from left drop-wrist, but there were no signs of a damaged brachial artery (the radial pulse being good). Sensation was lost in the musculo-spiral area of the fingers. The triceps acted. On the 26th an incision was made to expose the musculo-spiral nerve. There was no suspicion of the artery having been damaged, the radial pulse on that side being normal, but on isolating the nerve a wound was found in the side of the artery about a third of an inch long to which the nerve had been adherent by a small clot. There had been no general extravasation of blood. The nerve was found to have been pierced by the bullet, but a stout bundle of nerve-tissues remained intact on either side. The vessel was ligatured in two places and cut between. The nerve was not interfered with. On the 31st the sensation was returning in the fingers, but the drop-wrist was still present. It is remarkable that the bullet should perforate a nerve of this size and not completely sever it.

CASE 17. *Wound of the lung.*—Private —— was wounded on Jan 20th at an unknown range, probably 2000 yards. The entrance wound was immediately below the left sterno-clavicular joint. The wound of exit was at the eleventh intercostal space on the same side, one inch from the middle line of the back. The symptoms were *nil*. On the 31st the man appeared to be perfectly well.

CASE 18. *Wound of the pelvis.*—Private —— was wounded on Jan 20th at a range of about 1300 yards. The bullet entered two and half inches posterior to the tip of the left great trochanter, emerging one and a half inches vertically below the right posterior superior iliac spine. There was considerable rectal hæmorrhage but nothing could be felt on a rectal examination. The patient otherwise felt perfectly well. In this and other similar pelvic injuries it is difficult to understand the limited amount of damage apparently inflicted.

CASE 19. *Wound of the thigh, the pelvis, and the femur.*—Private —— was wounded on Jan. 24th at a range of 3000 yards. The entrance wound was at the central portion of the right gluteal fold. The wound of exit was two inches below and an inch in front of the apex of the left great trochanter. The base of the trochanter must have been traversed by the bullet, but there was no evidence of a complete fracture. There was a great amount of thickening and tenderness of the bone in the injured area, but no solution of the continuity of the femur. The external wounds were healed.

CASE 20. *Wound of the knee.*—Private —— was wounded on Jan. 21st at a range of 1400 yards. The entrance wound was immediately above the centre of the upper border of the left patella. The wound of exit was at the lower angle of the popliteal lozenge. There was slight effusion into the knee joint which still persists, but there is considerable mobility already present.

CASE 21. *Wound of the lung.*—Private —— was wounded on Jan. 20th at an unknown range. The entrance wound was a little external to and beneath the left sterno-clavicular joint. The wound of exit was at the ninth left costal interspace, immediately behind the posterior axillary line. There was hæmoptysis for three days, but there were no other symptoms. On the 31st he was quite convalescent.

These cases are for the most part sufficiently remarkable. The greater portion of the wounds were caused by the Mauser bullet and mostly all presented the characteristic features—a small circular slightly depressed area of the size of  covered by a black scab. The exit wounds were often quite similar, but a little larger, sometimes presenting a scar like an incised wound and difficult to discover. When I saw them a week or ten days subsequent to the injury they were for the most part healed. How these bullets fail to damage vital structures lying immediately in their path is nothing short of marvellous. The proportion of fatal chest wounds to those which are recovered from is believed to be small, but what the proportion precisely is cannot as yet be ascertained. It is abundantly clear that one lung and often both lungs may be traversed and in many directions without causing grave symptoms and often without producing any symptoms of lung injury at all. The large number of perforating abdominal wounds which are recovered from give pause to operative procedure in that direction, and the indications for operation in such cases must be completely revised. Wounds of the knee-joint seem also to be recovered from with a facility of which we have had no previous experience. The same may be said of wounds implicating other joints.

WILLIAM MAC CORMAC.

Mooi River, Feb. 1st.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

THE complete lull in the fighting on this side has had the effect of keeping our hospitals at the base comparatively empty, and nothing of moment has occurred since my last letter. The cases coming down now are mostly medical and are generally traced to exposure to the sun or to the use of unfiltered water. On the other hand, the hospitals on the Natal side are pretty full as the result of the Spion Kop and Acton Homes engagements.

The accompanying particulars of a case which I mentioned in a previous letter may be of interest to the readers of THE LANCET as illustrating the eccentricities of Mauser bullets.

Lance-Corporal —— of the Black Watch, aged 20 years, was wounded at Magersfontein on Dec. 11th by a Mauser bullet. The man was wounded from an unknown distance whilst lying on his face preparing to fire. The entrance of the bullet was over the left malar bone at its junction with the temporal bone. The wound, which was small and round, completely healed. The exit wound was about the lower angle of the right scapula, and this also healed. The patient was admitted into the hospital on Dec. 15th. He was entirely nervous on admission. There was but slight movement in all the muscles of the right arm, and sensation of this limb was much impaired. The sensation and motion of the right leg were good. The left arm was completely paralysed and the sensation was very much impaired. The patient could move the toes of the left foot, but the sensation of the left leg was much impaired, especially towards the extremity. The bladder and bowels had both emptied themselves automatically. As to respiration, the action of the intercostals was impaired on the left side. The patient complained of pain over the seventh cervical spine, and also tenderness in that position. There was also some tenderness in the left sub-maxillary region. His facial muscles were intact. He lay on his back with his head turned to the right side. There were no trophic changes anywhere. On Dec. 18th the patient had recovered tone in the bladder and the sphincter, and respiration, both thoracic and abdominal, was good. On the 20th the bladder and the bowels could retain their contents much better and the patient could move his left leg fairly well. Sensation also was improved. By the 25th there was a slight improvement in the sensation of the left arm and the left leg was still improving. There were no other symptoms. The patient was convalescent on Jan. 1st, 1900, and was sent home to Netley. At this time motion in the left arm was improving daily and sensation was good.

Enteric fever has claimed another victim in Major O. P. Walker, R.A.M.C., who died in Natal, aged 40 years. I am glad to say that the last reports of Lieutenant W. Jagger, R.A.M.C., who is suffering from the same disease, are favourable.

To-day (Feb. 7th) the *Spartan* brought down from Durban 370 wounded officers and men who will be distributed amongst the various general hospitals. The *Lismore Castle* is *en route* for Cape Town with 180 more. These are some of the 1020 wounded in General Warren's fights at Spion Kop, where, as you know, the killed, wounded, and missing amounted to the serious total of 1700, by far the heaviest losses we have sustained in any operation up to date. The enteric fever at Modder river and at Orange river is still very bad, as many as 70 cases being reported from the former place. The *Kildonan Castle* is leaving to-day for England with a large batch of sick and wounded and I hear that the outward transports have again dropped a great number of men for treatment in the Cape Town hospitals. I suppose that this is unavoidable to a certain extent, but still I cannot help thinking that more care might be exercised in the medical examination of men destined for duty at the front before they leave England, as some of these cases, notably cases of hernia, might easily have been detected prior to embarkation. These patients take up badly wanted accommodation in the various hospitals, and in many cases they never get further than the wards, from whence they are sent home again, costing the country money that might well be expended in other directions.

The frightful mortality amongst officers in the recent engagement, there being no less than 32 killed, 66 wounded, and six missing, seems to the lay mind to point to unnecessary exposure on their part, or to the enemy's well-known sharpness in detecting them in spite of the various means taken to make their appearance as similar as possible to their men. You will have received a more detailed list long before this reaches you; in fact, our last information regarding casualties was taken from a London paper. I have not had an opportunity of inspecting the new ambulance train yet, but from what I hear it is very complete.

The *Princess of Wales* has left for Netley with sick and wounded. She will be followed by the *Avoca*, which leaves to-day.

Claremont, Feb. 7th.

THE TREATMENT OF SOME FORMS OF APPENDICITIS AT PLOMBIERES WITHOUT OPERATION.

By SKENE KEITH, M.B., C.M., F.R.C.S. EDIN.

THE account of one case will give a very good idea of in what the treatment of appendicitis at Plombières consists. The history of the case in question evidently dated back to an attack of peritonitis some 12 years ago, when the patient was 23 years of age. So far as the patient can remember she was confined to bed for at least two weeks. The abdominal pain was very severe. Complete recovery followed this attack, except that from that time there was a disinclination to go up many stairs, as this brought on a feeling of tiredness in the right side and thigh. Indeed, on one occasion after going up a number of stairs while sight-seeing abroad, the patient was unable to sleep one night on account of the pain in the right side. In the autumn of 1895 she moved into a larger house, and although she felt the longer stairs a fatigue and went up and down as seldom as possible she was able to learn to bicycle in the spring of the following year and could go for from 20 to 30 miles in a day without setting up any of the pain in the side or in the thigh. In the beginning of 1896 she began to suffer from pain in the right side, and on examination the chief seat of the pain and tenderness was found to be midway between the umbilicus and the right anterior superior iliac spine. The bowels were attended to, some β naphthol was ordered, and a belladonna plaster was put over the whole of the right side. This treatment was followed by marked improvement, but the patient broke down on a journey to Italy and had to remain in Paris. At this time there was no pain, she was simply tired out. For about a month after coming back from Paris she was perfectly well, but towards the end of May the pain returned. On examination the appendix could be felt with the greatest ease. It felt almost as thick as my thumb. I do not think that it was in reality anything like so large as this, for my experience has been, while operating, that the appendix is actually smaller than it feels from the outside. This has also been my experience with diseased ovaries and Fallopian tubes, and I consider that one has always to discount a considerable amount of the apparent size. The patient was kept as quiet as possible and the treatment which had before been successful was renewed. The very slightest irregularity of the bowels was invariably found to increase the pain. A course of baths at Plombières was recommended, but the patient did not wish to waste her time by "going in for" a water-cure. Another physician was consulted and he independently advised a visit to the same place. The patient was undoubtedly of a gouty habit, and had there been no previous attack of peritonitis I would have diagnosed simply a gouty irritation of the appendix.

The patient went to Plombières at the beginning of August, 1897. The treatment consisted in 21 baths, taken one every day. She lay for from 40 to 50 minutes covered to the neck in the water, at not less than 34° C. and not more than 36° C. After the first few baths and for the last 10 minutes of each succeeding one the *douche Tivoli* was used. This is simply a spray of warmer water coming out of a rose somewhere about an inch in diameter, which, passing through the water of the bath, is allowed to play against the affected part like a feather. This is a most important point. If it be used too strong it seems to do harm, as there is almost certain to be an attack of pain when the douche is improperly used in this way. After the bath the patient had to lie down in bed for half an hour. If a patient goes to sleep at this time there is said to be a headache in the afternoon. Before leaving the patient was told by the medical officer (Dr. Bottentuit) and the bath attendants that she would require to return twice more. This she firmly resolved she would not do, as the treatment was so simple that she had absolutely no faith in it. Possibly owing to not being very careful at first the pain went away slowly and there were many complaints that the treatment at Plombières was nothing but "humbug." But by the beginning of the year 1898 the patient was quite well and was losing the habit of considering before going upstairs whether she really required to go. In the middle of June she suddenly broke down after bicycling about 12 miles and had to drive home. Pain and tenderness at McBurney's point were again found, though the appendix itself could not be made out. A second visit was therefore made to Plombières in August, much to the triumph of the bath attendant. Exactly the same treatment was carried out at this second visit as at the first. It is now 14 months since the patient felt any discomfort in the region of the appendix. She has bicycled 30 miles at a time and she can go upstairs without giving it a thought. For the first time in her life she has had this winter an acute attack of gout in her foot and still the appendix is giving no trouble.

One case in particular, where I removed the appendix, contrasts very markedly with that which I have just narrated. The history was simply of one acute attack followed by rapid loss of health and strength, accompanied by pain in the right side. The patient was a medical man, and it was evident that he would soon have to stop work altogether. There was no difficulty in feeling the appendix, and at the operation one narrow band of adhesion was found which bent the appendix at an acute angle, and in this way had first caused congestion and then inflammation of the appendix. As in this case the cause was a mechanical one no course of baths or any general treatment [illegible] been expected to do any permanent good. S[illegible] [illegible]terwards the pat[illegible] illness before the operation and the illness at the time of the operation, but he said that the misery experienced while his strength was returning was a thing he could never forget.

Plombières does not seem to be sufficiently known to the medical profession. It is probably the best place in the world for the majority of cases of chronic diarrhœa, and of late years it is coming to be recognised as a place where many cases of appendicitis may be cured without operation. The cases which do best are probably those where the appendicitis is, in part at least, due to some general condition. Quite a considerable number of patients have been sent who have not been cured of their appendicitis by the removal of the appendix! Many people may not care to go to France for pleasure at the present time, but as the healing art does not require to pay attention to political matters a short account may be of interest. Indeed, the place seems to be so little known that a hospital surgeon who had himself suffered from appendicitis had never even heard of it.

This bathing station is situated in a valley 1400 feet above sea-level, on a short branch line of nine miles, midway between Nancy and Belfort, and can be reached either directly from Calais or *viâ* Paris. English ladies travelling in the restaurant train from Paris had better secure their seats in the restaurant car by sitting in them when the train is full. The villagers are conservative; they oppose every innovation and have so managed that the railway ends at Plombières and can apparently never be continued beyond it. To do this they had to take what I am told was the finest part of the park which had been laid out by Napoleon III. at the time he had the new baths built. Napoleon's old bath-man is still in attendance, having put in 37 seasons without missing one day in all those years. One old woman over 80 years of age, who lives in the main street close to the old Roman bath, has never seen the railway or the new baths, though both are within one-third of a mile. She is, however, something of a character. The baths themselves are fairly good and there is an abundance of both hot and cold water. Indeed, the water comes up so hot that it has to be taken to a reservoir up the hill to cool it before it can be used. At one of the older establishments, mostly used for rheumatism, one can go down and see the water bubbling up The air there is so hot and steamy that it is somewhat difficult to penetrate to the lowest depths, and ladies should not go down when they have on any clothes which might spoil with damp.

The treatment for appendicitis appears to be what I have already described, with, in addition, the use of the *douche ascendante* when there is constipation. One peculiarity of the *douche Tivoli* is that the water feels warm when directed against a healthy part of the body but not when it is playing against the affected spot. During the course of the 21 baths the patient is, as a general rule, depressed and miserable, though this seems to be less marked when the weather is warm. The great thing required is to be content to do nothing. Patients may apparently lie in bed, sit at the band or in the casino, and may drive, but must not exert themselves at all. For anyone who likes to be dull and doing nothing I can recommend Plombières, although it is not the dullest of bathing stations. There is, however, one great objection to the place, and one which could be easily remedied. It is that no provision has apparently been made for providing proper food for those suffering from disorders of the alimentary tract. The medical officers put the best face on it and say that the waters are so beneficial that the quality of the food does not matter, although the meat provided is notoriously so hard as to be almost uneatable. I have travelled much in France and do not expect to find French meat very tender, but it certainly was a surprise to find the meat which I got at Plombières—a place devoted in large part to the treatment of gastric and intestinal disorders. There are several hotels and many lodgings and in one of these hotels the food was very good indeed. Although a man could go alone it would be too dull for a lady without a companion. I do not mean to say that a lady could not go alone, but to send any lady ill to start with and feeling worse at some part of the course would not be a very kindly act. It is not a very expensive place; the ticket from London direct by Calais is £4 12*s.*; no return tickets are issued. The rate at an hotel not attached to the new bathing establishment and within two minutes' walk of the baths per day and without wine is 10 francs and upwards. Baths and the *douche Tivoli* cost under 5 francs or less at the other bathing establishments in the town. Some of them seemed to be almost as comfortable as the new baths and the arrangements for the supply of water are exactly the same. A man who could take his baths without a break could do the whole course from London and back for about £32, including the medical officer's fees, "tips," and ordinary wine, but excluding the casino. The majority of ladies would not be able to get through a course quite so expeditiously, and a very pleasant way of utilising the break which usually occurs is by driving to Gerardmer and the Schlucht. Gerardmer is situated on the lake of the same name, over 2000 feet above the level of the sea. It is a very lovely spot and is said to be bracing; but it has the disadvantage of being very full in summer, too full, indeed, for comfort. From Gerardmer to the Schlucht, over 4000 feet high, is a drive of about three hours, through pine woods and passing hills and lakes. The German hotel, much better situated than the French, is about one mile across the frontier, and the view from it embraces the whole of the Münster valley. The return drive to Gerardmer can be made, in part, alongside the lakes instead of high above them.

The bathing season does not begin till June 1st and finishes in the end of September, July and August being the two months when the village is full of visitors and when literally there is not an empty bedroom. During these two months it is very necessary to engage rooms before starting. The beginning and the end—especially the end—of the season are to be avoided. Even the band stops playing before the end of September, while the theatrical company leaves at about the beginning of the month.

In my experience the treatment at Plombières is very successful in cases of chronic diarrhœa, in constipation (though at first sight this may seem peculiar), in mucous colitis, and in appendicitis. The baths—and the treatment is practically limited to baths, though many people drink a small quantity of water before lunch and dinner—are recommended for various other conditions, especially for rheumatism. Comparatively few English go to Plombières, though the numbers are said to be increasing.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(*Continued from p. 565.*)

LORD LLANDAFF'S Commissioners point out that before it is possible to determine whether purchase of the metropolitan water companies' undertakings is likely to be financially advantageous to the water consumers it is necessary to consider how the price to be paid will be fixed. They do not think it likely that the price can be settled by agreement. In the year 1880 an attempt was made by Lord Beaconsfield's Government to purchase the undertakings and the agreements arrived at were afterwards held by Sir William Harcourt's committee to be unsatisfactory, and since that date no serious attempt has been made to purchase by agreement. Many years ago negotiations which were entered into between the New River Company and the City of London had no result. The details were confidential.

In the year 1896 Sir Arthur Arnold, who was then chairman of the London County Council, entered into some negotiations with the chairmen of the water companies. As the result of the conversations which he had with them he came to the conclusion that some of the companies would be willing to sell their businesses on reasonable terms and that the purchase might be effected by agreement. The surviving chairmen of the companies through their counsel denied that the impression left on Sir Arthur Arnold's mind was well founded and denied also that any approach to an agreement was made.

In the year 1890 a Select Committee of the House of Commons, which was presided over by Sir Matthew White Ridley, examined several Bills, amongst which was one promoted by certain London vestries and parishes, which proposed that a water trust should be formed for the acquisition of the companies' undertakings under the Land Clauses Act with certain modifications, and a Bill was also framed to enable them to supply water from new sources. This Bill was not passed by the committee, but a special report was made on July 14th, 1891, in which it was recommended that the London County Council should be empowered to bring in a Bill constituting that body the responsible water authority for London and that they should be required to purchase alone or with the outlying authorities the undertakings of the eight metropolitan water companies, either by agreement or by arbitration within a fixed period. The London County Council considered the whole question and issued a report signed by Sir Thomas Farrer (afterwards Lord Farrer) in which they said that it was impossible to determine what should be paid for the water companies' undertakings without inquiry into the sources of supply and the nature and cost of new sources which might be necessary to replace or supplement those already existing, and these questions could not be determined by arbitration. It was contended also that an examination should be made as to whether the companies' charges were legal, whether their rating powers had not been stretched beyond the intention of Parliament, whether those powers might be reduced by Parliament, and whether competition with the companies might not be successfully resorted to. These questions, it was thought, would not be taken into account if purchase were conducted on ordinary arbitration terms, and if they were left out of account purchase would be likely to result in a manner unfavourable to the ratepayers and unduly favourable to the companies. This report was adopted by the County Council on Oct. 13th, 1891, and the Council declared that they were not able to accept the recommendations of Sir Matthew White Ridley's committee that they should purchase the companies' undertakings on the terms he suggested. A Royal Commission was then appointed to investigate the question of the London water-supply (the Balfour Commission), and when the Commissioners reported that the supplies in the valleys of the Thames and Lee were adequate in quantity and quality, subject to proper conditions of storage, filtration, and conservancy, the London County Council accepted the report "subject to criticism and to outlying facts and considerations," and Bills for the purchase of the water undertakings by the Council were introduced in November, 1894. In their Bills special clauses were inserted with regard to arbitration by which the arbitrators were required to have regard to the probability that the legal powers of a company as to taking water were limited; to discount the actual revenue because competition by other companies was possible; to revise the capital account because it represented obsolete works; to revise the revenue accounts in respect to repairs and renewals, and to take into account the likelihood of some competing body existing in the future. The arbitrators were not to allow any claim for back dividends for more than six years, nor to make allowance for a possible future increase of rateable value in unaltered premises, nor to give compensation in respect of compulsory sale. The Bill containing this clause was referred to a committee of the House of Commons (Mr. David Plunkett's Committee). The committee showed a manifest disinclination to accept the arbitration clause and the County Council proposed an alternative one which provided that arbitrators should not be precluded on any legal objection from considering any matter laid before them by either party and should deal with all the contentions of the parties as fully and effectually as could be done by Act of Parliament. The Commissioners suggest that this provision would apparently have enabled the arbitrators to decide upon the value without regard to the strict legal rights of the companies. Mr. Plunkett's committee did not give any final decision on this clause.

In the year 1897 the County Council again introduced Bills into Parliament for the purchase of the water companies' undertakings, and these Bills contained clauses giving unfettered discretion to the arbitrators and providing that they should not be precluded by any legal objection from considering all the contentions of the parties. On the second reading these Bills were rejected.

In 1899 the County Council again introduced a Purchase Bill in which they restored the clause which had been introduced in the Bill which was considered by Mr. Plunkett's committee. The Commissioners referred to the fact that during their inquiry they asked the London County Council whether that body were of opinion that the water undertakings could with advantage be purchased without any special terms of arbitration. The answer, which was very carefully drawn up, was given in writing. It has already been published *in extenso* in THE LANCET. The history of the arbitration clauses leads to the inference that the County Council think that in the interests of ratepayers and consumers purchase should not be conducted under ordinary terms of the Land Clauses Act, and the Commissioners discuss in some detail the contentions of the London County Council. 1. Stress was laid on the fact that the London water companies have no monopoly but are liable to competition. 2. It was contended that the companies are not entitled to charge the maximum rates and that a pledge had formerly been given to Parliament that these charges would not be made in the majority of cases. In answer to this the Commissioners point out that none of the special Acts contain any words restricting the companies from charging their maximum rates and that whatever pledge could be inferred from the language of the counsel for the water companies it was given with reference to a different scale of charges and one which was rejected. 3. It was contended that the capital of the companies should be revised because it included items which were not sanctioned by Parliament, and that it included sums spent years ago on works which had been abandoned or become obsolete. The Commissioners point out that the auditor of the London County Council gave it as his opinion that the capital of the companies as a whole represented "a going concern in good working order." 4 It was contended that the companies devoted too much of their annual revenue to dividends until they were able to pay the maximum rate to which they were entitled and that afterwards they were more lavish in their expenditure on improving their works. The case of the West Middlesex Company was brought prominently forward, but the Commissioners thought that the detailed account of expenses given by the secretary of the company which showed how the increase of expenditure had arisen proved that it was an "accidental coincidence" that the increase in capital outlay had occurred when it did. 5. It was contended that no compensation should be given to the shareholders of the companies in case of purchases for the amount due to them for back dividends. The Commissioners opine that the legal rights of the companies to pay back dividends to their shareholders are incontestable. 6 It was contended that Parliament did not intend that the rating powers of the companies should be "stretched to the utmost." The Commissioners state that in their opinion the check which Parliament intended to make is the one which they actually did make—that is, a limitation of the dividend—and that as soon as the maximum dividend is reached, the back dividends paid up, and the reserve fund built up the extra receipts must be applied to the reduction of charges made to the consumers for the water supplied. In the case of the New River Company this check has not been imposed. The company have not been restricted from making their full statutory charges. The rating powers of the companies are various and ambiguous and the authorised charges increase with the rateable value although the premises may not be altered. In the case of two of the companies, however (the Chelsea and the Kent), the increase in rateable value has had the effect of lessening their receipts, as they themselves have had to pay more on the increased assessments imposed on them than they have gained by assessments imposed on their customers. The Commissioners say that variation in the water charges allowed by the statutes of the different companies do not supply good grounds for attacking their revenues as inequitable. In case of purchase by arbitration it appears that any arbitration to ascertain the value of the companies must proceed upon the basis of their statutory rights and that the arbitrator could not take upon himself to consider whether Parliament might curtail them and then assign to the companies a lower compensation on the ground of the probability of such interference with existing statutory rights, and it is precisely in order to enable the arbitrator to take that course that the special arbitration clauses have been framed. The Commissioners, however, assume that if the policy of purchase be adopted the price of the undertakings should be determined by an arbitration conducted on the lines of the Lands Clauses Act, although possibly, in view of the magnitude of the undertakings, the tribunal might be differently constituted.

The Commissioners, having come to the conclusion that should the water companies undertakings be bought it should be done under the conditions laid down by the Land Clauses

Act, proceeded to consider what the financial results of arbitration would be likely to be.

The advisers of the London County Council, they point out, have looked with some apprehension upon the possible results. In the Bill which was introduced by the London Vestries in 1891, by which it was proposed that the undertaking should be purchased by a water trust and that the amount of payment should be settled under the Land Clauses Consolidation Act, the Parliamentary Committee of the County Council reported that there were *primâ facie* grounds for believing that such a method of purchase would prove unsatisfactory, because (1) recent Stock Exchange quotations had been unduly large; (2) unduly large dividends had been maintained; (3) the works and plant of some of the companies were obsolete; (4) no sufficient allowance had been made for depreciation; and (5) a heavy outlay would have to be made for establishing a new supplementary system of supply.

The Water Committee of the London County Council, after considering the report of their Parliamentary Committee, came to the conclusion that if the matters mentioned were left out of account in valuing the undertakings the people of London might be made to pay a very large amount for the existing undertakings and then find it necessary to spend from 10 to 20 millions more money in providing a new supply. Such a purchase, therefore, they thought should be resisted at all hazards. And, again, on Dec. 5th, 1895, their Parliamentary Committee reported to the London County Council that if the arbitration clause which they wished to put in was not inserted the arbitrator might be able to make an allowance for "compulsory sale" and for back dividends, and that therefore the purchase should not be undertaken in that case without full consideration of the probable financial results.

The Commissioners report that they had not the advantage of hearing any estimate as to the probable cost of purchase and that therefore they found it necessary to form for themselves the best estimate they could as to what would be the award of a fair and just arbitrator, acting on the usual terms of arbitration in cases of compulsory purchase and valuing the undertakings of the water companies at what they are worth to the vendors, having regard to their existing rights and taking into account the existing advantages and disadvantages of each company.

The estimate must in the first place be made on the existing net income of each company. The arbitrator ought next to consider whether the income is stable or unstable and in doing so he would have to find out what future capital expenditure would be necessary to maintain the income, bearing in mind that the companies are under an obligation to maintain the proper supply of water for the whole of their respective districts. The shareholder ought to receive a sum sufficient to purchase an equally good security producing the same income which he was getting from his water shares. A calculation made on these lines would result in neither loss nor gain to the purchaser, who would have the equivalent, and no more than the equivalent, for what he paid; and if the purchaser were able to borrow money on security of rates as well as water charges, and if he had, moreover, the option of paying in cash the amount of compensation awarded, he might obtain an advantage from the first from the fact that he could borrow money at a lower rate of interest than the water shares were now earning.

In the purchase of the undertakings the arbitrator would have to bear in mind that in some companies there was possibly a prospective increase of income, for which an arbitrator should make allowance. On the other hand, there might be companies in which the income was likely to diminish. "Assuming a claim for prospective increase were established the arbitrator would have to ascertain its true value and to discount that value in respect of the present payment."

It is usual in the case of unwilling sellers that some compensation should be made for compulsory sale, but nothing in the Lands Clauses Act requires an arbitrator to award anything for this, and it is not correct to say that any custom has grown up under the Act which binds arbitrators to make such an award. It is true that in some cases awards have been made because of the compulsory character of the sale as a *solatium* to the owner dispossessed of property to which associations of family or personal interest attached. But it would be improper for an arbitrator to give any compensation in the nature of a *solatium* of that kind for deprivation of water shares. The shareholders would be entitled to be recouped for any delay which might occur in finding an equally good investment yielding the same income and to be recouped for the cost of the re-investment. The amount which should be allowed would depend on the character of the shares of the particular company concerned, and although it could hardly be estimated it would probably be comparatively small.

Should the undertakings be purchased by a public authority it would be according to custom that a sinking fund should be set aside by the purchasing authority to repay the amount borrowed within a certain number of years. It would, of course, be within the power of Parliament to allow a purchasing body to dispense with such a sinking fund, but this would be contrary to precedent.

Considering, however, the magnitude of the operation it might not be unreasonable to allow the operation of the sinking fund to extend to 80 or even to 100 years, should the sinking fund be considered necessary. Unless the purchased income exceeds the interest on the purchase money the whole of the annual charge which would have to be met for providing that fund would have to be got either by increasing the water charges or by a special rate—i e., by making the water consumer pay more for water or by imposing a new burden on the ratepayer, whether he consumes water or not. At the end of the time allotted for the operation of the sinking fund great relief would be given to the community, but in the meantime for many years an increased burden would have to be borne.

The Commissioners pass on to consider to what extent it is likely that the expense of a sinking fund would be met by any economies which might be ensured by a public authority. Amongst the possible ones it had been suggested during the inquiry that about £50 000 a year would be saved in (1) directors' fees; (2) salaries, &c.; (3) collection of rates; and (4) printing and stationary. With regard to possible saving in directors' fees the Commissioners thought that some compensation to the present directors would probably be thought necessary by Parliament, and it is not unlikely that this compensation would for some time absorb a great part of the suggested saving (£28,345 per annum).

It was suggested that £5000 per annum might be saved i salaries and superannuations, but the Commissioners thoug it doubtful whether management of a business as large that carried on at present by the eight companies, if do by an unpaid committee whose members would be frequen changed, was likely to result in economy. The perman officials would have more responsibility, with the result t they would obtain higher pay. One of the witnesses had experience in the municipal management of w undertakings (at Blackburn, Nottingham, and Burnley) sidered that a larger staff, more office work, and more re ing were required under municipal than under a comp management. Under municipal management the Co sioners say that a motive to economise and the experience necessary to economise rightly are both wanting.

With regard to saving in the collection of rates one of the witnesses had estimated it at £10,000 a year. During the year 1897 the companies paid £51,884 for collecting, and it was suggested that a public authority might be able to employ the parish rate collectors in getting the water rates. This suggestion did not appear to be a practical one, for it was found that municipalities which managed their own water-supply found it necessary to employ a separate staff of collectors for the water rates and the borough rates. In the case of Liverpool the collection of the sanitary rate is made by the water rate collectors and the borough rate is collected separately; the water rate collectors receive 4 per cent. of the total money taken—a higher percentage than that which is paid by the London water companies. The difficulty of collecting water rates is increased by the fact that extra charges for baths, stables, gardens, &c, are made and that the trade supplies are given by meter and at special rates according to the quantity taken.

Another possible source of saving was that of Parliamentary expenses. This, the Commissioners observe, is purely hypothetical, for although it is true that the annua purchase bills of the London County Council would b saved if that Council were the purchaser the purchasin authority would have to make applications to Parliament f extending its powers in the same way that the companies present have to make them. Moreover, the expenses of arbitration leading up to a purchase would be very heavy.

It was suggested that a saving of £5000 a year stationary and printing might be made if the undertakings were bought from the companies. The Commissioners agreed with Sir John Lubbock that a public authority was likely to spend more rather than less on that item.

In the case of purchase of the undertakings by a public authority one of the most important changes which would take place has regard to the Chamberlain's Sinking Fund. The Sinking Fund clauses are, the Commissioners point out, peculiar to metropolitan water legislation. The first Sinking Fund clause was introduced into an Act of the East London Company in the year 1886 at the instance of the City of London. Three similar forms have been adopted in the case of other companies and now in some form the clause has been applied to all the companies. In detail there are differences in the form of the clause introduced, but the operation in each case is substantially the same and has the following effect: "*Whenever a company obtains power* to borrow money on debenture stock—and since 1886 no company has obtained power to increase its capital in any other way—the clause assumes that the money so borrowed earns profit at the average percentage of the dividend or interest paid on all the capital of the company, whether share capital or loan capital. The excess of that average percentage over the interest payable on the debenture stock issued *plus* 1 per cent. for management of such debenture stock is taken as the profit earned by the new capital and the company are required to pay the whole of the excess to the Chamberlain of the City of London as trustee for the purpose of purchasing and holding shares of the company and of investing the dividends thereon with a view to ultimately extinguishing the capital of the company or for such other purposes as Parliament may from time to time determine." This clause prevents any additional value accruing to the undertaking from the new loan capital and withdraws from the profits of the company the sum paid over to the Chamberlain for the benefit of possible purchasers in the future. Parliament required the City Chamberlain to re-invest payments which were made on account of the Sinking Fund and the dividends accruing from them in purchasing the shares of the company which made the payment. The transfers of the stock purchased are taken by the Chamberlain in his own name with the description, "Chamberlain of the City of London." The accounts of the Chamberlain's Sinking Fund have not at present been published with the other accounts of the Corporation, but in future they will be included with the notion that their responsibility will thereby be established.

The intention of the clauses, the Commissioners point out, was that fresh borrowing powers should be granted to the companies only on condition that the future profits assumed to result from the additional expenditure should be appropriated for the benefit of a purchaser representing the interest of the public.

Up to the present time the practical result of the clauses has been small, the dates when payments to the Chamberlain become due have not yet arrived, but there are, taking all the companies together, £6,320,000 of debentures subject to the Sinking Fund clause. In the year 1887 the sum of £4804 was paid to the Chamberlain, and it is estimated that should the present dividends of the companies continue unaltered no less than £119,703 a year will be payable in and after the year 1915, and it may be safely asserted that the operation of the Sinking Fund clauses will provide a very substantial sum.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON: THE REPORT FOR 1899.

As we have already mentioned, the annual meeting of the General Council of the Prince of Wales's Hospital Fund for London was held on Feb. 13th at Marlborough House, the PRESIDENT (H.R.H. the Prince of Wales) being in the chair, and the draft report for the past year was read and adopted. The total receipts for the year 1899 showed an increase of about £9,000 over those of 1898, and the total sum distributed for the year was £42,000. At the close of the meeting H.R.H. the PRINCE of WALES said that it only remained for him to perform what might seem a formal duty, but one which in reality was one of pleasure—namely, most heartily and sincerely to express his thanks to the Council and honorary officers of the Fund. Proceeding the Prince of Wales felicitously congratulated Sir William MacCormac who, he said, was absent at the seat of war. "At his time of life," said His Royal Highness, "the performance of the arduous duties that this necessitates reflects, I think, the greatest credit on him and gives the utmost satisfaction to all who know him."

The report, which showed an eminently satisfactory state of matters, was as follows:—

The General Council view with satisfaction the work of the Fund during the past year, as shown by the reports of the several committees appended hereto. It will be seen that the general policy adopted at the inauguration of the undertaking has been continued, and while money has not been hoarded unnecessarily the total distributed has left a balance on the right side. The receipts for 1899 are £48,536 15s. 4d., as against £39,272 3s. 5d. of the previous year. This result the Council consider highly satisfactory under the peculiar circumstances of the year. This is more especially the case, seeing that in view of the exceptional claims upon the public the committee decided not to make the usual autumn appeal. It is, however, a noteworthy fact that of all the sums received not one has been in the form of a legacy, although the hospitals themselves derive a large proportion of their incomes from this source. But now that the Fund is proved to have come to stay it is hoped that exceptions to this rule may be introduced from outside the ranks of existing subscribers.

The total sum distributed for 1899 amounted to £42,000. Of this sum £26,250 has been given as annual grants and the balance as donations. It will be seen that in the majority of cases the grants have been given on certain conditions. The cost of management and collection is about 3¾ per cent., as compared with about 6¾ for 1898. As stated by His Royal Highness the President, improvement is evident from the fact that the receipts are larger and the expenses smaller. There has been no clashing with the work of either the Sunday or Saturday Funds, and the promise given to that effect has been kept. Subscribers may be interested to know that most of the surplus copies of the Jubilee programme printed for the benefit of the Fund have been given to London hospitals, board schools, workhouse infirmaries, and other institutions.

In the report of the Hospitals Distribution Committee it will be noted that a distinction is drawn in those cases in which grants are withheld between the ten institutions which, though favourably reported on, did not at the end of last year appear to be in urgent need of further help and the three which were not deemed to be hospitals in the true sense of the word. This distinction is drawn by the advice of the Visiting Committee and in accordance with requests frequently published in the public press. The effect of the work for the year is that, in addition to improvements in operating theatres or rooms, nurses' accommodation, sanitary and other requirements, 45 more disused beds will be re-opened and maintained, making a total of 287 re-opened in the last three years through the help of this Fund. Rather more still remain closed, but in many of these instances the beds could not easily be re-opened at the present time. In some hospitals the vacant wards are used for pay patients and thus fulfil a useful purpose, which makes it desirable to defer the consideration of re-opening these beds as free. In others they are used for nurses, and if they are devoted to their intended purposes fresh accommodation must be provided for nurses. In still harder cases the debts of the hospitals must be liquidated before any fresh liabilities are incurred. In the course of the present session a petition will be presented to Parliament by the Central Hospital Council calling attention to the heavy rating of hospitals. In support of this, on behalf of the Fund, a petition has been forwarded in accordance with the instructions of the Executive Committee, expressing the sympathy of all concerned and their desire to see the rating of all recognised London hospitals abolished. It may now be considered that the expenses of the Fund have been reduced to a minimum. Every care is taken that the money subscribed be wisely spent. Therefore, the General Council would earnestly request all interested in the cause to support the Fund in the present year, when the hospitals will be called upon to admit the wounded and when more than ever public charity is apt to turn from the sufferers at home to those abroad. Demands must shortly be made on the hospitals, not only for their increasing number of patients, but especially this year for soldiers and sailors returning from South Africa in need of good nursing and tender care. In conclusion, the Council confidently appeal to all their generous supporters including the Press, to aid them in maintaining the established and successful position of the Fund.

THE BACTERIAL TREATMENT OF CRUDE SEWAGE.

IT is abundantly clear that before we are able to pronounce definitely upon the merits of the bacterial treatment of sewage the evidence of long practical experience must be at hand. Nothing would seem to be simpler than that sewage should be spread upon a large area of porous material and there left to liquefy and ultimately to be converted into inoffensive products by the agency of bacteria. But of course sewage is not a simple organic mixture. If it consisted solely of fæces, water, and urine, bacterial agencies would be equal to the task of purifying it to a remarkably high degree. The difficulty even with the chemical treatment of sewage has been owing to the presence of matters like paper, fat, fibre, factory refuse, &c.,

which are hard to disintegrate. The same substances present a serious obstacle to the completion of the work of purification by bacteria. In the coke beds at Crossness and Barking there occurs a deposit of them which decreases the sewage capacity of the coke bed. A series of gaugings of the capacity of the 13 foot coke bed, for example, showed that the decrease of capacity was proceeding at the rate of 1 per cent. of the original capacity per week. Dr. Clowes, the chief chemist to the London County Council, undertook experiments with a view of preventing or minimising this choking of the coke bed, for it threatened a short life to the filter. As might have been guessed the deposit upon the coke consisted largely of cellulose or chaff, straw, and woody fibre, all of which are materials which baffle any attempt at disintegration by bacteria and, further, which close the pores of the coke. Attempts were therefore made, and with some success, to separate this woody sediment by allowing the sewage to settle slightly in a wooden trough. The sediment so obtained was inoffensive and contained from 52 to 70 per cent. of combustible matter. By adopting this simple preliminary the rate of choking of the coke bed was reduced from about 1 per cent. per week of its original capacity to 0 64 per cent. It is hoped that further trials will show that even a higher success in this direction is attainable.

The bacteriology of the deposit which accumulates upon the coke beds is of interest. Dr. Houston remarks that the organic matter is probably of such a nature as to resist the action of bacteria for a very considerable time if not almost indefinitely. The number of bacteria found per gramme of deposit was 1,800,000. Even this large number of microbes does not account for the deposit, for Dr. Houston has found that this number of typhoid bacilli, for example, weighed only 0·0000147 gramme. The character of the microbes appearing in the cultures differed somewhat from those found in crude sewage. Thus there was an increase in the number of spores of bacillus enteritidis sporogenes and a decrease in the number of bacillus coli. Proteus-like germs were present in abundance as were also the bacillus arborescens and an allied form. The bacillus prodigiosus was also isolated. Inoculations of a guinea-pig with some of the deposit developed an abscess at the site of inoculation and later the same characteristic red-colour-forming bacillus was isolated from the pus of the abscess. Mice similarly inoculated died with the characteristic symptoms of tetanus and bacilli were noted which in form were indistinguishable from the tetanus bacillus. Further experiments left little room for doubt that the tubercle bacilli are present in important numbers, but apparently they have lost for the most part their infective power. Dr. Houston sums up the bacteriology of the deposit in three sentences. In crude sewage, he writes, in bacterial coke beds, and in the effluent from bacterial beds, there are certain bacteria which, after being stained with hot carbol-fuchsin resist decolourisation with 33 per cent. nitric acid. Some of these "acid-fast" bacteria cannot with certainty be morphologically distinguished from the tubercle bacillus. In one instance a guinea-pig inoculated with the deposit accumulating on the coke bed died and presented on examination the appearance of death from tubercle infection, and sections of its organs when appropriately stained showed the presence of numerous tubercle bacilli.

These interesting results appear in a report recently published by the London County Council and their significance turns on the question as to whether the effluent discharged into a stream is used for drinking purposes or not.

THE LEICESTER MEDICAL SOCIETY: CENTENARY DINNER.

THE centenary of the Leicester Medical Society was celebrated on Feb. 27th by a dinner in the County Assembly Rooms, Leicester, which was attended by members of the medical profession from all parts of the country. Dr. Frank M. Pope (President of the society) occupied the chair, and was supported by the Archdeacon of Leicester, the Mayor of Leicester, Sir William Broadbent, Sir J. Sawyer, Sir Felix Semon, Sir Thomas Wright, Dr. W. S Church (President of the Royal College of Physicians of London), Dr. F. T. Roberts (President of the Medical Society of London), Dr. J. B. Spence (President of the Medico-Psychological Association), Mr. J. Tweedy (Vice-President of the Royal College of Surgeons of England), Mr. T. Bryant (President of the Royal Medical and Chirurgical Society), and Dr. Dawson Williams. Amongst those present were Dr. H. Michie (President of the Nottingham Medical Society), Mr. C. H. Hough (President of the Derby Medical Society), Dr. Howes (President of the Lincoln Medical Society), Mr. R. Taylor (chairman of the Leicester Provident Dispensary), the chief constable of Leicestershire, the town clerk of Leicester, and other local public gentlemen.

The CHAIRMAN, in giving the toast of "The Queen," referred to the Queen's visit that day to Netley. Such a journey must have been very fatiguing to one of Her Majesty's advanced years, but it was satisfactory to learn that she had been cheered on her way by the information received from the seat of war—information which had made them all cheerful. And if there was anything which would render that toast more acceptable at a gathering like the present it was that Her Majesty had always been mindful of her medical men and had on many occasions shown them her warm esteem.

The health of the Prince of Wales having been submitted from the chair and drunk with much enthusiasm, and

Mr. C. DOUGLAS having submitted "The Navy, Army, and the rest of Her Majesty's Forces," and the toast having been duly acknowledged,

Sir WILLIAM BROADBENT gave the toast of "The Leicester Medical Society." Dwelling on the value of such societies he said he thought there were no organisations such as this which did not serve a useful purpose. Meetings were held, papers were read, discussions were initiated, and opinions were exchanged, all of which tended to the benefit of the profession. A man could not read a paper before a medical society or venture on criticism without thinking the subject over and putting his own ideas in order, which was an exercise of great value not only to himself but to the other members of the society. At such meetings one found the young man fresh from lectures and hospital laboratories meeting the man of ripe experience. The man of ripe experience might from the young man realise the progress which had been made since his time, and the young man might find his theories shattered against the walls of ripe experience. In both instances a great service was rendered and marked progress was ensured. Another important work of medical societies was the bringing together of the members of the profession. By this means jealousies and suspicion were mitigated and honourable competition advanced. One of the great objects of such societies was to sweeten the moral atmosphere and to keep down quackery, which sometimes permeated into their ranks. There was another point for which they were indebted to these medical societies and that was that no one could attend their meetings without learning something of the advancement made in medical and surgical knowledge, and in that respect alone the work of such societies was of the greatest possible value. It was just 100 years since the Leicester Medical Society was started. He should have liked to have brought before them what had been done in regard to their profession in that period in London, but he had not the time at his disposal to do so. One of the things, however, which struck him in looking at some of the records of those days was that they had just had an epidemic of influenza, when the medical societies of London issued a circular with a number of questions on influenza The questions could not be better put to-day and the answers were very instructive. He noticed that among the answers was a very interesting one from Leicester from a Mr. Butler. In replying to the question as to what were the symptoms he was one of the few who "reserved his opinion." Another question which exercised the public mind of that day was vaccination. He found that Manchester resolved to give the poor the benefit of vaccination and money was voted for gratuitous vaccination. He was perfectly aware that in saying this in Leicester he was treading on dangerous ground. He thought for the first time in his life he had that day made the acquaintance of an anti-vaccinationist, though he did not venture to discuss the question, as he was well aware that one might just as well try to discuss the beautiful sunset with a colour-blind man as vaccination with an anti vaccinationist. But he thought that in the future the process would undergo development. They were vaccinating actively at the present moment against typhoid fever, and he thought they would sooner or later see vaccination adopted for protection against most contagious diseases. Reverting to the toast Sir William Broadbent wished the Leicester Medical Society every success and resumed his seat amid applause.

The CHAIRMAN, in replying to the toast, said they appreciated Sir William Broadbent's kind and sympathetic speech. No one was better qualified to tell them what a medical society should be. Their society, as they knew, was just celebrating its centenary. It was established, he believed, mainly for the circulation of books. It met twice a year and held its meetings at what he presumed was the chief hotel of the time. The members ordered three books and then feasted. Unfortunately, little was known of those very early days of the society, but undoubtedly by the circulation of literature it supplied a great want. The society in those early days comprised amongst its members two eminent surgeons, Mr. Thomas Paget, senior, and Mr. Thomas Paget, junior. He was thankful to say that they had had good surgeons in Leicester ever since. He knew of no town where there was such a fraternal feeling among the members of the medical profession as at Leicester and he attributed that state of things very largely to the work of their society.

Mr. C. J. BOND proposed "The Royal College of Physicians and Surgeons and the Learned Medical Societies," and in the course of his remarks said that medical politics should only be directed to obtaining for the medical profession a better opportunity of doing their true work.

Dr. CHURCH, Mr. TWEEDY, Dr. ROBERTS, and Mr. BRYANT responded.

The MAYOR of LEICESTER, in responding to the health of the Mayor and Corporation, referred to the improved sanitary condition of the town and said that the corporation in their endeavour to make the town clean and healthy had succeeded in reducing the death-rate from 23 per 1000 to something between from 14 to 18 per 1000. In short, they had done their best to reduce the incomes of the medical profession. With regard to small-pox he believed that by adopting the system of isolation they had in Leicester succeeded in preventing the spread of that disease. He was glad to find other towns following their example. He and the Sanitary Committee would be glad at all times to coöperate with the medical profession in any way they possibly could.

Mr. G. C. FRANKLIN gave "Our Guests," and the Archdeacon of LEICESTER, Dr. WARD COUSINS, and Sir JAMES SAWYER responded. The toast of "The Chairman" concluded the proceedings.

THE
APPOINTMENT OF EXTERN EXAMINERS IN THE ROYAL UNIVERSITY OF IRELAND.

A MEETING of the Senate of the Royal University of Ireland was held on Feb. 8th, when Dr. W. A. MCKEOWN brought forward the following motions:—

1. That extern examiners be appointed in the Faculties of Arts and Medicine, so far as the funds of the Royal University will allow.
2. That a committee be appointed to inquire as to the examinations in these faculties in which extern examiners are most required and as to the funds which are now or hereafter could be made available for the payment of such examiners.

In support of these suggestions Dr. W. A. McKeown has issued a most important statement in which he says that his chief reason for proposing these motions is that the examinations of the University are regarded generally by the public, by teachers, and by students, and even by members of the Senate, as unfair, mainly through the peculiar constitution of the examining boards, and that the appointment of extern examiners would certainly lessen that unfairness and do great good in other ways. To ascertain the grounds for this prevalent belief Dr. McKeown proceeds to investigate the relations of the Royal University with the students and with the colleges. He explains what an immense advantage the students from University College, Dublin, and the Catholic University School of Medicine have, as in one-half of every examination they are examined by their own teachers, whilst the students from other colleges are examined only in a small part by their own teachers. As a result he holds that the awards of prizes, &c., by the Royal University since its foundation have been vitiated and unreliable, the prizes obtained by students of these two schools having been obtained with odds greatly in their favour, whilst the prizes obtained by other students have been gained with the odds greatly against them. Dr. McKeown says that on the actual examinations doubtless the successful candidates were entitled to their prizes, &c., but under more equitable conditions other candidates might have been the fortunate winners, and other persons might have competed. As showing how, in his opinion, the constitution of the boards of examiners may affect the examination Dr. McKeown gives in his pamphlet the following table:—

Table showing the Subjects for the Final Examination for the Degrees of M.B., B.Ch., B.A.O., and the Institutions in which the Examiners Teach.

—	Belfast.	Cork.	Galway.	Catholic University School of Medicine	Richmond Hospital.
1. Medicine, Theoretical...	—	—	1	—	1
2. Medicine, Clinical	—	—	1	—	1
3. Medical Jurisprudence	—	1	—	1	—
4. Hygiene	—	1	—	1	—
5. Surgery, Theoretical...	—	—	—	1	1
6. Surgery, Clinical .	—	—	—	1	1
7. Surgery, Operative	—	—	—	1	1
8. Ophthalmology and Otology	—	1	—	1	—
9. Midwifery and Diseases of Women and Children .	1	—	—	1	—
10. Pathology ...	1	—	—	1	—
—	2	3	2	8	5

This table shows the relative position of the students from the various schools to the examiners in the Final M.B. Examination, a position which is made still more evident, he thinks, by the following table.—

Table showing the Number of Persons from Various Medical Schools who have obtained the Degree of M.B., B.Ch., B.A.O., in the Years 1889, 1894, and 1899.

—	1889.	1894	1899.	Total.
Queen's College, Belfast	32	21	27	80
Queen's College, Cork...	15	8	11	34
Queen's College, Galway	2	—	1	3
Catholic University School of Medicine	6	5	10	21
School of Physic, Trinity College ..	5	1	—	6
College of Surgeons, Dublin	—	1	—	1
London School of Medicine for Women...	—	1	—	1
Durham University	—	1	—	1
Mixed returns—i.e., where a student has been educated at more than one school	10	—	2	12
	70	38	51	159

Dr. McKeown says the number of Fellows and examiners approximately which should represent the different schools at the final medical examinations on the basis of graduation compared with what such schools really have is as follows:—

Belfast	with 80	graduates	should have	11½	but has	2
Cork	,, 34	,,	,,	5	,,	3
Galway	,, 3	,,	,,	½	,,	2
Dublin—						
Catholic University School of Medicine	,, 21	,,	,,	3	,,	8
Richmond Hospital	,, —	,,	,,	—	,,	5

Dr. McKeown points out that the position of the Richmond Hospital in relation to the Royal University requires explanation, and says that the constitution of the boards of examiners is unfair to all the schools and colleges except to

University College, Dublin, and the Catholic University School of Medicine, both of which have a predominant influence in all the examinations of the University.

Dr. McKeown brought his two motions before the members of the Senate on Feb. 8th at their meeting, when after a discussion a committee was appointed to examine the financial state of the University with the view of ascertaining how far it would be possible and desirable to appoint additional and extern examiners. Subsequently all the old Fellows and examiners in the Faculty of Medicine were re-appointed, with the addition of Professor Lindsay (Belfast) in medicine and Professor W. N. Thompson (Belfast) in physiology.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7084 births and 5387 deaths were registered during the week ending Feb. 24th. The annual rate of mortality in these towns, which had increased from 21·2 to 25 8 per 1000 in the three preceding weeks, declined again to 24·2 last week. In London the rate was 21·5 per 1000, while it averaged 25 9 in the 32 provincial towns. The lowest death-rates in these towns were 9 9 in Croydon, 13 7 in Cardiff, 16 9 in Birkenhead, and 17·6 in West Ham; the highest rates were 37 3 in Blackburn, 39 0 in Salford, 40 7 in Wolverhampton, and 44 7 in Preston. The 5387 deaths in these towns included 444 which were referred to the principal zymotic diseases, against numbers increasing from 428 to 469 in the three preceding weeks; of these 120 resulted from whooping-cough, 115 from measles, 92 from diphtheria, 47 from "fever" (principally enteric), 40 from diarrhœa, and 30 from scarlet fever. No fatal case of any of these diseases occurred last week in Brighton; in the other towns they caused the lowest death-rates in Swansea, Birkenhead, Halifax, and Gateshead, and the highest rates in Wolverhampton, Blackburn, Preston, and Sheffield. The greatest mortality from measles occurred in Wolverhampton, Leicester, Preston, and Sunderland; from whooping-cough in Portsmouth, Norwich, Salford, and Leeds; and from "fever" in Wolverhampton. The mortality from scarlet fever showed no marked excess in any of the large towns. The 92 deaths from diphtheria included 48 in London, 10 in Sheffield, six in Liverpool, and four in Portsmouth. No fatal case of small-pox was registered last week in any of the 33 large towns, but 11 small-pox patients were under treatment in the Metropolitan Asylums Hospitals on Saturday last, Feb. 24th, and three new cases were admitted during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2009, against numbers decreasing from 3578 to 2052 on the 14 preceding Saturdays; 160 new cases were admitted during the week, against 174, 157, and 159 in the three preceding weeks. Influenza was certified as the primary cause of 52 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had been 423 and 527 in the two preceding weeks, declined again last week to 485, and were 62 below the corrected average. The causes of 67, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Leeds, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Manchester, Blackburn, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had risen from 23 0 to 31·0 per 1000 in the six preceding weeks, further increased to 31·7 during the week ending Feb. 24th, and exceeded by 7·5 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15 2 in Leith and 24 7 in Aberdeen to 39 1 in Dundee and 62·4 in Perth The 931 deaths in these towns included 19 which were referred to diarrhœa, 17 to measles, 17 to whooping-cough, nine to scarlet fever, five to diphtheria, and two to "fever." In all 69 deaths resulted from these principal zymotic diseases, against 61 and 82 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·3 per 1000, which was 0·3 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had increased from eight to 20 in the three preceding weeks, declined again to 19 last week, and included eight in Glasgow, four in Aberdeen, and three in Edinburgh. The deaths from measles, which had been 19 and 24 in the two preceding weeks, declined again last week to 17, of which nine occurred in Glasgow, five in Dundee, and three in Paisley. The fatal cases of whooping-cough, which had risen from eight to 18 in the five preceding weeks, decreased again to 17 last week, and included nine in Glasgow, three in Aberdeen, and three in Perth. The deaths referred to scarlet fever, which had been three and 11 in the two preceding weeks, declined again last week to nine, of which five were registered in Glasgow, two in Edinburgh, and two in Paisley. The fatal cases of diphtheria, which had been seven in the preceding week, decreased to five last week and were all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 172 to 325 in the four preceding weeks, further rose to 362 last week, and were 129 above the number in the corresponding period of last year. The causes of 42, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·7 and 42·4 per 1000 in the two preceding weeks, further rose to 51 0 during the week ending Feb. 24th. During the past four weeks the death-rate in the city has averaged 36 7 per 1000, the rate during the same period being 21·1 in London and 26·7 in Edinburgh. The 342 deaths registered in Dublin during the week under notice were 58 in excess of the number in the preceding week, and included 11 which were referred to the principal zymotic diseases against 17 and 15 in the two preceding weeks; of these five resulted from measles, four from diarrhœa, one from scarlet fever, one from "fever," and not one either from small-pox, diphtheria, or whooping-cough. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·2 in Edinburgh. The deaths referred to measles, which had declined from 18 to one in the six preceding weeks, rose again last week to five. The fatal cases of diarrhœa, which had been two in each of the three preceding weeks, increased to four last week. The mortality from scarlet fever corresponded with that in the preceding week, while that from "fever" showed a decline. The 342 deaths in Dublin last week included 51 of infants under one year of age and 121 of persons aged upwards of 60 years; the deaths of infants and elderly persons being respectively 11 and 40 in excess of the numbers in the preceding week. Eight inquest cases and four deaths from violence were registered, and 182, or more than one-half, of the deaths occurred in public institutions. The causes of 11, or more than 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE under-mentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—Johnston Hamilton Acheson, John McElwee, D'Arcy Harvey, Reginald Thomas Alexander Levinge, John Christopher Ferguson, and Edward Pain Mourilyan.

The following appointments are notified:—Surgeons: J. P. H. Greenhalgh, lent to Royal Marine Infirmary; J. F. M. McDougall to the *Rodney*; and N. J. Roche to the *Alexandra*.

IMPERIAL YEOMANRY.

The appointments of the undermenioned gentlemen as Medical Officers, with the temporary rank of Captain, are cancelled:—H. Manders, M.D. (Major, 1st Volunteer Battalion Princess Charlotte of Wales's, Royal Berkshire Regiment); R C Dun, M.B.; C. Smith, M.D.; A. C. Fry, M.R C.S.; E. T. Vint M.B.; C. B. Howse, M.R.C.S.; and H. A. Lownds (Captain, 2nd Volunteer Battalion the York and Lancaster Regiment). Francis Wellford, M.B. to be Medical Officer, with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Major M. T. Yarr has arrived at Portsmouth for duty. Brigade-Surgeon S. K. Ray, A M.S., retired pay, has arrived n the Eastern District for duty. Major John Semple retires rom the service receiving a gratuity. Lieutenant Douglas as left for South Africa.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel C. B. Stoney, having resigned his Militia appointment, ceases to belong to the Army Medical Reserve of Officers.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the retirement from the service of the undermentioned officers: Lieutenant-Colonel William Flood Murray, Bengal Establishment. Lieutenant-Colonel Andrew Duncan, Bengal Establishment. Lieutenant-Colonel Edward Fawcett, Madras Establishment.

VOLUNTEER CORPS.

Artillery: 6th Lancashire: William Thomas Blackledge to be Surgeon-Lieutenant. *Royal Engineers:* 2nd Cheshire (Railway): Surgeon-Captain T. C. Bailey resigns his commission. *Rifle:* 2nd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant P. D. Minchin to be Surgeon-Captain. 3rd Volunteer Battalion the Northumberland Fusiliers: Surgeon-Lieutenant W. H. Vickery to be Surgeon-Captain. 1st Volunteer Battalion the Essex Regiment: Surgeon-Lieutenant A. B. Harris resigns his commission. 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): George Robert Fabris Stilwell, M.B., to be Surgeon-Lieutenant. 3rd (Sunderland) Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant J. C. Fenwick to be Surgeon-Captain.

TRANSVAAL WAR NOTES.

The Chelsea Hospital for Women offers special facilities for the gratuitous treatment of the wives of reservists suffering from diseases which come within its province.

The x ray apparatus, the gift of the Duke of Newcastle to the *Princess of Wales* hospital ship, has proved of great service in locating the position of bullets in the wounded. The apparatus was supplied by Harry W. Cox, Limited, of Cursitor-street, W.C. *The x ray apparatus on board the Spartan* and *Trojan* were also supplied by this firm.

Captain G. S. Walker, R.A M.C., died from enteric fever at Ladysmith on Feb. 23rd.

Captain Holt, R.A.M.C., died from wounds received during Sir R. Buller's operations at Modder river on Feb. 21st.

Lieutenant Mackenzie, R.A M.C., was wounded in the Koodoosberg reconnaissance on Feb. 7th.

At a meeting held in Birmingham on Feb. 26th, a committee was formed to assist the general committee of the Royal Army Medical Corps Fund in London. Mrs. Bennett May and Mrs. Lloyd Owen were appointed hon. secretaries.

Major G. E. Hale, R.A.M.C , D.S.O., has been appointed by the War Office military commandant of the bearer company in connexion with the Imperial Yeomanry Hospital.

The medical staff of the Princess Christian Hospital left Waterloo on Feb. 28th for Southampton, where they embark on the *Assaye* for South Africa. The following is a complete list of the medical staff:—Major H. B. Mathias, D.S.O., R A.M.C., the War Office representative, in command; chief surgeon: Mr. J. Paul Bush; medical officers: Dr. G. V. Worthington, Dr. E. A. Nathan, and Mr. A. T. Flemming; dressers: Mr. A. B. Oridland and Mr. E. M. Pearse.

The general committee of the Sick and Wounded Officers' Surgical and Medical Aid Fund, of which the Duke of Abercorn is president, have made arrangements whereby the best professional advice will be at the service of officers returning invalided from South Africa. Leading physicians and surgeons have placed their services at the disposal of the committee, and numerous offers of hospitality to invalids and convalescents have been received. Considerable funds will be required to meet the expenses involved in skilled nursing or special treatment over long periods and of costly surgical appliances. Subscriptions should be sent to the honorary treasurer, Hampden House, Green-street, W.

The following surgeons have been appointed to serve with the Welsh Hospital for South Africa:—Professor Thomas Jones, F R C.S. Eng., Professor of Surgery, Owens College, Manchester, and surgeon to the Manchester Royal Infirmary; Mr. J. Lynn Thomas, F R C S. Eng , assistant surgeon to the Cardiff Infirmary; and Mr. R. H. Mills-Roberts, F.R C S. Edin., surgeon to the Llanberis Quarries Hospital. Alderman Sir David Evans has consented to act as treasurer to the hospital. Meetings are being held and local collections are being made in different parts of Wales and in the large provincial towns to press the claims of the hospital among Welshmen. The committee desire that it should be known that the hospital is intended for the use of the Imperial troops, irrespectively of nationality. A Welsh national concert is to be given in aid of the funds at the Queen's Hall, London, on March 14th at which Mr. Ben Davies has kindly promised to sing.

SIR J. SIVEWRIGHT'S AMBULANCE CORPS.

Mr. Allan Johnson, one of the three British members of the South African Medical Corps organised by Sir James Sivewright for ambulance service with the Boers, sends to the *Times* a full account of the remarkable adventures of that expedition. Although the Transvaal Government had wired to Cape Town "politely but firmly" declining their services they were induced to proceed to Delagoa Bay, where they had an interview with Mr. Pott, the Transvaal Consul, who told them curtly that they were not wanted, declaring that there were no wounded to require their care. Mr. Pott's object appears, however, to have been only to get rid of the British element in the corps. The Afrikander members, who had remained discreetly in the background so long as the corps had to deal with the British colonial authorities at the Cape or at Durban, now claimed complete control over the expedition, and, in spite of the official refusal of the Transvaal Government to have anything to do with the corps, they had no hesitation in accepting the friendly assurances of a Boer whom they met "fortuitously" at Lorenzo Marques that their services, if volunteered not collectively but individually, would be accepted. The British members naturally regarded these strange developments with suspicion, and, believing them to be at variance with Sir James Sivewright's intentions, as they undoubtedly were at variance with the conditions under which the expedition had been organised, Dr. Gray, the leader of the British section, sought to retain the equipment of the expedition until Sir James Sivewright's wishes had been elicited. Sir James, however, telegraphed that they were to be handed over to the Afrikander leader, Dr. Neethling, who proceeded with the other Afrikanders under special passports to Pretoria. Mr. Johnson says, in conclusion, it was clear "that while the Transvaal Government were quite willing to receive any number of Afrikanders into their service they would not look at an ambulance corps which included Britishers, especially if these showed that they meant to stick tenaciously to their pledge to work for the wounded of every sort and race without prejudice in the interest of humanity alone."

ARMY MEDICAL SCHOOL, NETLEY.

The eightieth session of the Army Medical School at Netley commenced to-day, Friday, March 2nd. 35 surgeons on probation (18 for the Indian Medical Service and 17 for the Royal Army Medical Corps) will attend the session. The following are correct lists of the surgeons on probation. It is believed that a large number of probationers are to be nominated for the Royal Army Medical Corps:—

SURGEONS ON PROBATION, R A.M.C. NAMES IN ORDER OF MERIT.

T. Biggam.
H. Richardson.
C H. Carr.
W. L Baker.
T. W. Cotton.
E Bennett.
F. M Parry.
B R Dinnis.
J. S Twigg.
W. J. P. Adye Curran.
J. Powell.
R. L. Argles.
J. G Foster
F. P. Lauder
E. G. Ford.
T. S. Walker.
L. M. Purser.

SURGEONS ON PROBATION, I.M.S. NAMES IN ORDER OF MERIT.

J. D. Graham.
C. A Sprawson.
W. H. Cazaly.
W. V. Coppinger.
P. A. Browne.
A. Spitteler.
M. MacKelvie.
L J. M. Deas.
W. G Hamilton.
J. C. S. Oxley.
H. R. Macnee.
W. Lapsley.
W. D. A. Keys.
A. Chalmers.
J. Good.
W. M. Houston.
G. J G. Young.
S. R. Godkin.

The following district order has been issued at Aldershot: "As the welfare of the patients in hospital is in a great measure dependent on the class of men detailed for duty as orderlies thereto, the general commanding desires that the greatest discrimination should be exercised in the selection of these men and only those of good character and who can read and write are to be employed on this important duty."

THE LEGION OF HONOUR.

We recently mentioned the names of several French medical officers who were made members of the Legion of Honour in recognition of their gallant services and we now have the pleasure of recording yet another addition to the distinguished roll. By a presidential decree dated Dec. 24th, 1899, Dr. Nestor Léonce Parin, medical officer of the second class in the Navy, was promoted to the grade of Chevalier of the Legion of Honour, the feat for which he obtained the reward being thus described: "At Tonkin, on Nov. 29th, 1896, during the action of Pinh-Nan-Tai, Dr. Parin went forward under a brisk fire in order to dress the wounds of four soldiers." The same gazette also records the advancement to the grade of Officer of M. Nicolas Chalmé, apothecary in chief to the Navy, with over 34 years' service, inclusive of five years and seven months afloat. The new officer's knighthood dates from June, 1886.

CLUB METHODS.

To the Editors of THE LANCET.

SIRS,—Possibly the following experience of club methods with their medical officers may be of sufficient interest to warrant its publication. I should first explain that the Hand-in-Hand Benefit Society is a small local society which pays its surgeons twice a year for work done in the same way practically as the more widely-known National Deposit Society—namely, for visit and medicine 2*s.* 6*d.*; consultation and medicine 1*s.* 6*d*; repetition of medicine, 1*s.* After I took over this practice five years ago I was surprised to find my payment at Christmas replaced to the extent of 5*s.* by a receipt for an honorary member's subscription, and with this a note from the secretary addressing me as "Dear Brother" and simply asking for a receipt. There was never at any time any request that I should become an honorary member.

For the first few years I made no objection, but once when the payment for the half-year amounted to 7*s.* 6*d.* I declined having this honour thrust upon me. At the end of last year a payment of £1 1*s.* was due to me and there came back a cheque for 16*s.* and the usual receipt. I returned the receipt and explained that I had no desire to become an honorary member and pointed out that there was nothing in their rules making such a step necessary. I received a reply saying that such a course was customary, but on my insisting the payment was completed. Some days afterwards I received a letter, a copy of which is appended hereto as Enclosure A. My reply to this letter is also appended as Enclosure B. I do not think that any further comment is necessary.

I am, Sirs, yours faithfully,
C. SCOTT WATSON.

Parkside, Wonersh, Guildford, Feb. 24th, 1900.

[ENCLOSURE A.]

Hand-in-Hand Benefit Society,
17, Friary-street, Guildford,
Feb. 14th, 1900.

DEAR SIR,—Your letters of Jan. 25th and Feb. 1st were duly laid before the committee of the above society on Tuesday last and I am instructed by them to inform you that owing to your refusal to pay honorary subscription of 5*s.* your name is to be taken off the list of the societies' surgeons from this date. Therefore, if you have any account against the society from December, 1899, to Feb. 14th, 1900, I shall be glad to receive same.

Yours truly,
Dr. Scott Watson. J. FOSTER, Secretary.

P.S.—I may add that the agent of your district has been informed that your name is taken off the surgeons' list for the Wonersh district and another medical gentleman appointed.—J. F.

[ENCLOSURE B.]

Parkside, Wonersh, Guildford Feb 17th, 1900.

SIR,—I am in receipt of the letter from your committee dated Feb. 14th. Of course, it is a matter of very little importance to me whether my name is taken off the list of the society's surgeons, but the whole proceeding is so extraordinary that I desire to make the following remarks on it to your committee.

In the first place, there is no *rule* that a medical officer shall become an honorary member, and it is distinctly wanting in ordinary courtesy to dock his Christmas payment of the subscription without even asking his permission. Secondly, the subscription is not a large sum, but it is 5 per cent. on a yearly payment of £5, an amount which I certainly did not receive from the society last year and have, I think, very rarely received during the five years I have been here. Third, the members whom I have here are people who, if not in the Hand-in-Hand, would cheerfully pay my ordinary lower fees of 2*s.* 6*d.* or 3*s.* 6*d.* per visit and from 2*s.* to 2*s.* 6*d.* for consultation and medicine at my own house. I have taken the trouble to go over several half-years taken at random. *In one—the first half of 1897—I find that the patients* I attended for you for £4 7*s.* would have paid me as private patients £6 0*s.* 6*d.* and equally without any bad debts. In another half-year *21s. for 28s.; in another £2 9s. for £3 7s. 6d., and so on.*

I want to show that your medical officers, if they are situated as I am, are doing you a distinct and substantial favour by attending your members at the fees you pay. For the privilege of doing you this favour you charge them 5*s.* a year, and not only so but you stop this sum out of their payment for work done without even a "by your leave," and if they object you take their names off the list of the society's surgeons. *This procedure is so curious that I propose to send* an account of it to THE LANCET.

I am, Sirs, yours truly,
Mr. J. Foster, C. SCOTT WATSON.
Secretary, Hand-in-Hand Benefit Society, Guildford.

"PRODROMAL RASHES IN MEASLES."

To the Editors of THE LANCET.

SIRS,—The writer of the interesting annotation on prodromal rashes in measles in THE LANCET of Feb. 24th is not quite accurate when he states that the question of these rashes does not appear to be even entertained in English works. He will find that attention is drawn to the subject both in Dr. J. W. Moore's "Eruptive and Continued Fevers" (p. 138) and in the "Manual of Infectious Diseases" by Dr. Washbourn and myself (pp. 96 and 167). Dr. Dawson Williams also alludes to it in his article on Measles in Dr. Clifford Allbutt's "System of Medicine" vol. ii., p. 111. In these books it is particularly stated that these rashes may lead to errors in diagnosis, and especially to mistaking measles for scarlet fever. Secondly, Trousseau, before Henoch, appears to have been well aware of these eruptions, as may be seen by referring to his "Clinical Medicine," vol. ii., p. 214, of the New Sydenham Society's Translations, where in mentioning the date of appearance of the specific rash of measles he says: "I perceive, gentlemen, that I am causing you to take up an erroneous impression; I already hear some of you reminding me that I have several times shown you in our nursery wards infants in whom at the second day of the fever of measles small efflorescences were visible in situations where the skin was hot and covered with perspiration. On the next day, or the day after the next, there was scarcely a trace of these efflorescences to be found."

I am, Sirs, yours faithfully,
Homerton, Feb. 27th, 1900. E. W. GOODALL.

DESTRUCTION OF SUPERFLUOUS HAIR BY THE ROENTGEN RAYS.

To the Editors of THE LANCET.

SIRS,—Referring to some remarks I made at the meeting of the Thames Valley Branch of the British Medical Association at Kingston-on-Thames on Nov. 15th, on the beneficial therapeutic effects of the Roentgen rays on certain eruptions of the skin, I can now say that those cases are all doing well. In that of a woman, aged 33 years, who consulted me on Oct. 13th for a growth on each side of the chin of about 30 dark hairs about from half to three-quarters of an inch long, I administered seven exposures of the x rays, with the result that she had slight dermatitis, which got well in about a fortnight. All the hairs have disappeared and show no signs of return. I also had opportunities of seeing a case from the London Skin Hospital, Fitzroy-square, of a young girl, aged 23 years, with numerous dark hairs, which had grown freely on both sides of the face, after 18 exposures, had slight dermatitis and in a month after the last exposure the hairs had completely disappeared. Much care has to be exercised in the length of time of exposure and the number of exposures and regulation of ampère metres in the treatment of these cases.

Two other ladies since, one 25 and one 27 years of age, have had six and seven exposures successively and the skin shows slight electrical dermatitis, with the same successful results. The roots and sheath, when examined microscopically, show a drying up of the hair bulb and root sheath. The exposures in all these instances are less than noted by Dr. Neville Wood in his interesting article on a case reported by him in THE LANCET of Jan. 27th. I opine that we are in a position to say that we now have a very useful method of treatment in these hitherto troublesome growths of hair and an improvement on the tedious method of destruction by electrolysis.

I am, Sirs, yours faithfully,
Jan. 30th, 1900. JAMES STARTIN.

THE ORGANISATION OF THE PROFESSION.

GREAT YARMOUTH.—BENEFICIAL EFFECTS OF THE MEDICAL LOCK-OUT.—EVERY PRACTITIONER IN UNION.—WELCOMING AND HELPING THE JUNIORS.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from page 577.)

WITH regard to the medical officer of the lodge of female Foresters who had been persuaded by the medical union to withhold his resignation for three months pending negotiations a favourable settlement was obtained, though unfortunately it did not last long. At the end of the three months the female Foresters' lodge accepted the terms brought forward by the medical profession and appointed a medical officer on these conditions. But in the course of time this medical officer did not care to continue the work even on the higher and better terms. He found that the women were always ill, or imagined that they were ill, and gave him far too much trouble. In the interval there had been angry controversies between the women and the men Foresters. The latter had engaged in a struggle on behalf of the women and the women had been the first to desert them. Now, the better to fight the medical profession the men's societies had amalgamated with other similar friendly societies and had opened the Great Yarmouth Amalgamated Friendly Societies' Medical Institute, where they employed a salaried surgeon to do all their work. This was an opportunity for the women to return into the fold by joining the institute. Their medical officer, it was urged, wished to resign, what better could they do? And accordingly they joined the institute just opened by the friendly societies.

The Yarmouth branch of the Incorporated Medical Practitioners' Association had also to consider the position of the medical men who were employed by the London and Manchester and other insurance companies. These companies sent out paid canvassers who touted and practically advertised their medical officers. To serve such companies was incompatible with the principles advocated by the medical union, but nevertheless it was necessary to proceed with caution and slowly. It is no use to urge medical men to give up a portion of their income unless there is a well-disciplined and strong organisation to support them. Besides, it was well known that these companies would import strangers. Therefore the resignations were sent in gradually. This, however, did not prevent the insurance companies from importing outside medical men, but by the time they came the union had grown in strength and fixity of purpose, so that the newcomers were boycotted. The medical union also appointed a committee to watch the Midwives Bill. At first they were inclined to oppose the Bill and wrote to that effect to the Members who represent Yarmouth in the House of Commons. The Liberal Member promised to support the arguments of the members of the profession and the Conservative Member fenced with the question. The medical men themselves, however, did not at first know much about this subject. The committee whom they had appointed to study the details thought that it would not be prudent to oppose the Bill in its present stage. This was in 1897. The report of the committee concluded in favour of allowing midwives to attend cases of natural labour where there was no danger and no need to use instruments. They urged that midwives should not be permitted to give certificates of still-birth, and that those midwives who claimed to be placed on the register on the ground of previous experience should first be made to give satisfactory evidence of their proficiency. It was also thought that the penalties ought to be increased from a possible fine of £5 to £20. Both the Members of Parliament now expressed their readiness to support amendments in favour of these suggestions The medical union also agreed to depute their executive to wait on the licensing bodies and on the General Medical Council so as to explain the various grievances which they were attempting to reform.

By the end of 1896 the friendly societies had accepted the proposal to amalgamate, but in practice they did not join simultaneously. The different societies came in one by one as their terms of agreement with their respective medical officers came to an end. They rented a large house, which had formerly been occupied by a well-known medical practitioner. The upper part was used as a residence for their senior medical officer, and the lower part was converted into a surgery, a dispensary, an office, and a waiting-room, &c. By the time all the benefit societies had joined them they had to employ a junior or assistant medical officer. The medical practitioners of Yarmouth at once decided not to meet these medical officers of the Friendly Societies' Medical Institute in consultation. Consequently the institute sent up to Norwich for consultants, but the Yarmouth Medical Union appealed to their Norwich colleagues and sent a deputation to explain matters. To the honour of the members of the profession practising at Norwich it should be noted that they warmly responded and unanimously refused to act as consultants for the Yarmouth Friendly Societies' Medical Institute. The resolution to boycott the medical officers of the institute was adopted on Jan. 29th, 1897, and as a consequence some of the patients had to be sent to London. Unfortunately the metropolis is so immense that the work of organising the profession in London progresses but slowly, otherwise the consultants of the capital would have acted like those of Norwich.

In seeking to organise the profession at Yarmouth great care has been taken to encourage and welcome young practitioners and new-comers. The recently qualified practitioner must begin to work somewhere, and if organisation means only the creation of monopolies for the older and established practitioners the movement will certainly break down. To encourage such selfishness would weaken—indeed, it would completely wreck—the cause. By encouraging younger men and impecunious beginners they soon become loyal and devoted members of the medical union. Otherwise they will be compelled to act as outsiders. The great desire has been to give the struggling practitioner honourable appointments and patients. By keeping the interests of the poorer members of the profession constantly in view and being ever mindful that juniors as well as seniors have to live, much has been done to create a real feeling of brotherhood and genuine devotion to the cause of medical union. Formerly a great amount of work was done by unqualified medical assistants who attended to midwifery cases, &c., but to-day there is not a single unqualified assistant in Yarmouth, and those medical practitioners who employ dispensing chemists keep them strictly to the work of dispensing. While the Yarmouth branch of the Incorporated Medical Practitioners' Association thus deals actively with all ethical and economical questions, there is for the reading and discussion of purely scientific papers the Yarmouth Clinical Society which is open to all. Then for convivial purposes there is the old Medico-Social Society and thus each organisation has its special and distinct purpose and no clashing can occur.

The question of establishing yet a fourth organisation was raised and debated for some time. It was proposed *to follow the example of the practitioners of* Eastbourne and Coventry and to establish a medical service and a scheme to that effect was prepared. But it became very evident that the medical practitioners objected to contract work in any form, and therefore, they asked, why should they themselves organise such work? In some places and under the stress of special circumstances it might be necessary to do so, but it was felt that no such stress existed at Yarmouth. While the Yarmouth practitioners remain in their present frame of mind it seems quite evident that nothing of the sort will be attempted. But circumstances may alter and strong outside pressure *may* be brought *to* bear For *instance, if a* great many members were to secede from the Friendly Societies' Medical Institute some form of medical aid would have to be provided for them. These members would not be taken back on the old terms and many of the senior practitioners would not care to take them back on any terms. Indeed, this is a growing sentiment of which the friendly societies would do well to take into account before they push matters too far. A medical practitioner who has several clubs, at first, and very naturally, hesitates to give them up But when he has once done so, and in the course of time discovers that he can get along just as well without them, nothing will induce him to revert to this form of practice. It is far too irksome and insufficiently remunerative. If a medical service was organised by the profession it is probable that only the junior practitioners would consent to act as its medical officers. The establishment of a medical service at Yarmouth would therefore prove very advantageous to the younger *practitioners.* The members of such a service would have a larger choice of medical men but they would not get the senior practitioners. On the other hand, even the junior practitioners are now so well satisfied with their position that they are not at all keen on the subject. Therefore the project of a medical service is in abeyance: the scheme is ready to be brought out should the necessity arise.

Among the other questions discussed was that of the stamping out of all forms of canvassing. On this the medical union felt strongly and acted with energy. Strict measures were taken to prevent canvassers making use of the names of any medical man. Undeterred by this the National Deposit Friendly Society sent an agent to Yarmouth and endeavoured to establish a branch in that town. This society pays its medical officers according to a tariff that is much higher than usual in such business; but, on the other hand, it recruits a much higher class of members. Of course, they have no wage limit, and therefore the members of the Yarmouth Branch of the Incorporated Medical Practioners' Association all refused the positions that were offered to them. After several vain efforts the society had to abandon the attempt and withdrew its agent from the town. Here, then, was a distinct victory and much future trouble and loss were avoided by making, at the onset, a determined and united resistance. Unfortunately there is generally an exception to the best of rules. Though the members of the profession at Yarmouth are wonderfully united and unanimous there was one medical man who stood out against them. It has always been a matter of great difficulty to know what to do in such cases. To refuse to meet in consultation such a person is about all that can be done, but in this case there was another weapon available. The practitioner in question happened to hold a public appointment, and according to the regulations he was bound to have a deputy. Naturally all the members of the medical union refused to act in this capacity. He thereupon appealed to the medical officers of the Friendly Societies' Medical Institute and offered to become their consultant if one of their two medical officers would act as his deputy. This proposal was accepted and his difficulty seemed to be at an end, but fortunately for the cause of the medical union a difference took place and the medical officers of the institute refused to act as deputy for the Poor-law medical officer, so that the latter had to appeal once more to the members of the medical union. One of the members of the medical union then consented to act as his deputy on his promising to cease his opposition to the medical union. He has already given up the clubs which employed canvassers, and it is probable that at its next meeting he will be elected a member of the Yarmouth branch of the Incorporated Medical Practitioners' Association. This medical union will then possess 17 members, who comprise all the medical men of the town who are in active practice. The two medical officers of the Friendly Societies' Medical Institute are thus absolutely isolated. Those who want to contract for medical aid must either accept the terms laid down by the members of the medical profession or join the Friendly Societies' Medical Institute. In 1898 a young medical practitioner established himself at Yarmouth. No sooner had he arrived than the secretary of the medical union called upon him and persuaded him to join. Soon afterwards he was offered the post of medical officer to a club. The position offered was such that he would have readily accepted it, but he thought that it was his duty first to consult the other members of the profession, and they had no difficulty in explaining to him that he should refuse the appointment. This he did, and now that he is better acquainted with all the circumstances he fully realises that the advice given him was to his own advantage as well as to the advantage of the profession as a whole. Indeed, it is very useful for young men who have not yet acquired experience in these matters, to find, on establishing themselves, that there is a strong union, composed of the most experienced men, ready to give them the best advice and all possible help and support. When thus taken in hand early these new-comers become very faithful and useful members of medical organisations.

In the commencement of the year 1899 it was found that the work of organisation had been so thoroughly done that it was no longer necessary to hold monthly meetings. It sufficed that the executive should meet once a month and the district committee should meet every three months. The question of hospital abuse was now taken in hand. All the members of the hospital staff are also members of the medical union. The ticket system prevails and there are about 4000 tickets distributed in the course of the year giving the bearer a right to six weeks' treatment. Undoubtedly this leads to some abuse among the out patients, though notices are posted on the wall and warnings issued that the hospital is a charity and only meant for the poor. The hospital medical staff have now made arrangements that except in urgent cases they will not take more than 50 new patients in any one day. This gives 12 new patients to each member of the staff and as the number is thus limited they receive fuller attention. By having more time to devote to new patients there is a better chance of discovering cases of abuse and these are reported to the committee of management. Some improvement has been effected, but the present state of affairs is still considered unsatisfactory.

To return to the question of club practice it may be noted that according to the annual report dated Dec. 31st, 1897, there were at that time 27 branches of various registered friendly societies at Yarmouth. These possessed 4534 male adult members, 1129 juveniles or boys under 18 years, and 349 wives and daughters of members. The children under six years numbered 481. This gave a grand total of membership of 6493. The increase during the next 12 months amounted to only 327 more members, which is but a small amount considering not only the natural increase of the population but the fact that the friendly societies freely accepted as members both women and children. Indeed, the increase of adult male members in 1898 only amounted to 45. But many labourers have come to the town since who wish to belong to some medical aid organisation and who know nothing of the disputes. The chief objection made by the members of the friendly societies is not to the payments which the members of the medical profession demand, but to the wage limit and the exclusion of women and children. The adults, whether men or women, pay 4*s.* a year, the juveniles 2*s.* 6*d.*, and there is a sliding scale for children under six years of age. If a young man joins as an adult member when he is 18 years of age the probabilities are that he will give his medical attendant but little trouble for many years, but if a woman joins she is almost certain to be ill during the very first year. As a rule the complaints are not serious and are mostly to be attributed to some form of neurosis, but this does not give the medical attendant any the less trouble. At the Friendly Societies' Medical Institute there is but one waiting-room and here a great number of patients congregate and have to wait for a long time under very unwholesome conditions. Many members complain of being kept waiting so long, and it is a curious and significant fact that the leaders who advocated the formation of this institute are themselves careful not to employ the institute medical officers, but go to private practitioners and pay full fees. At first the institute refused to pay sick allowances on medical certificates given by others than their own medical officers, but what with pressure of work and the ever-increasing number of members who resort to the private practitioners the certificates given by the latter are accepted when countersigned by the senior medical officer of the institute.

In 1898 the Yarmouth Friendly Societies' Medical Institute had 6820 members, with the result that there were 25,166 attendances at the dispensary, 10,955 visits paid to patients at their own houses, and 22,452 prescriptions dispensed. The senior medical officer was paid £305 and the junior medical officer £180. If we divide this total of £485 by the 36,121 visits and attendances the result is a trifle over 3¼*d.* for each medical consultation. As the total amount paid by the members for medical aid during the same year was £1224 18*s.* 5*d.* it will be seen that the institute realised a good profit out of its medical officers' work. Even if we make a liberal allowance for the value of the premises occupied, for the dispensing, and for the drugs it is probable that the medical officers are sweated to the extent of £300 or more a year. The position of the junior medical officer is so arduous and so badly paid that they all leave in a very short time. When the institute was first organised the members were led to believe that they would spend less than *formerly.* This has not proved to be the case and the subscriptions have not been reduced. They had to borrow £300 from the bank to furnish their premises and this complicates the situation. The institute also provides various little plums for its promoters. The secretary receives £20, the porter £36, the treasurer £12 10s., sums which constitute a substantial addition to an artisan's income. The medical officers got midwifery fees of 10s. 6d., but there were only 67 births during the year, so that this does not constitute a large addition to their income. These medical officers depend solely on the institute and have to be careful to give the fullest attention to the members of the committee with the result that the ordinary members complain that they are neglected, especially in times of epidemic; consequently those who can afford it resort to a private practitioner, and the latter are now well satisfied with having got rid of their clubs.

As a case in point, a local practitioner explained to me that he used to attend two branches of the Eastern Star Provident Association. The members were all adult males and paid 4s. a year, so that the dispute about women and children did not affect them, nevertheless one of these branches suddenly left him and without even giving notice. He used to receive from this branch £14 a year. Some time after they had left him one of the members fell ill and sent for him and paid him the ordinary fees. After an illness of six months these amounted to £13 7s., and the bill was duly honoured. Had the practitioner, who gave me this information, been still acting as medical officer to this society the patient in question would only have paid 4s. That is to say, that the ex-medical officer received nearly as much from one patient as he used to receive from the entire branch, and he is well satisfied with being dismissed from club work. Starting from this instance to review his entire practice he found that he had received from the various Yarmouth clubs £325 10s. during the year 1896. Then came the medical lock-out and in 1897 he only received £49 1s. from the clubs, yet his total income for the year was only £40 7s. less than usual. Thus the increase in private practice compensates for the loss of the clubs and there is much less work to do. This experience was confirmed by several other practitioners and they all said that they were very glad to get rid of the clubs. This would not be the case if the clubs consisted of the right class of members. As at present instituted club practice cannot be properly carried out. For instance, one local practitioner explained that he had 100 railway servants under his charge. During the recent epidemic of influenza 11 of them were ill. If 11 per cent. of the members of the institute were to be taken ill simultaneously the two medical officers could not possibly attend all the sick. Indeed, it has been noticed that they do not visit their patients often enough and their visits are so brief that even in cases of influenza they not infrequently find their time too short to take the temperature. Formerly, when nearly all the practitioners at Yarmouth had clubs, the patients used to complain when they were neglected and the medical officer was summoned before the committee of his club. To-day, however, it is not much use complaining to the Friendly Societies' Medical Institute. The committee know full well that their medical officers are overworked, and therefore they feel that they are themselves indirectly to blame for any neglect that may occur. The ordinary members, however, are beginning to understand that the system does not work to their advantage and that they are not always tended with the necessary attention and care. Thus it becomes a matter of public interest that this system should be abolished or thoroughly reformed. The large number of members of the Friendly Societies' Medical Institute who prefer to pay for private practitioners, and do so, is a proof first of abuse and secondly that the medical aid given is not satisfactory. Indeed, the figures given above are a mathematical demonstration that the medical officers of the institute have too much to do, and therefore there must be some negligence. In the course of time, this fact will be more and more clearly realised and then we may expect still further changes. It is fortunate that the medical profession at Yarmouth is so well organised and is fully prepared to meet the exigencies of the situation as from day to day it is developed and modified.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Course of the Epidemic.—Plague in Australia.—The Extent of the Famine.—Lumsden's Horse.

PLAGUE is still on the increase. There have been 1869 deaths returned for the past week as against 1768 for the week previous. The increase is chiefly in Bengal, where 624 deaths have occurred as against 339 for the week before. It is reported that 604 deaths have occurred at Patna and in the district around. These figures are manifestly incorrect, as 87 deaths have been reported for Calcutta alone. In Bombay city the general mortality keeps fearfully high, 2400 deaths having occurred during the past week, a rate of 162 per 1000 per annum. For Feb. 7th 408 deaths have been returned, which is the highest on record. Small-pox appears to be increasing considerably. This simultaneous occurrence of another zymotic fever epidemic with plague is quite a new feature, as hitherto relapsing fever was the only infectious disease which has occurred along with plague. Cholera and dysentery have been exceptionally scarce. Unless the small-pox epidemic develops much more severely I shall expect to see a speedy decline of the general mortality as the high rate has now continued for several weeks and according to the indications of previous outbreaks it should now very soon rapidly decline.

Plague continues to attack various villages in the Punjab in a sporadic form. In Karachi, however, an improvement is reported. There is an increase in the Mysore State and Bangalore City and Cantonment.

In Calcutta the returns show more living cases discovered as well as deaths attributed to plague. In view of the outbreak at this season last year these facts are particularly ominous. The cold season in all parts of India attacked by plague is now practically over, so that its further development should convince those who hold to the seasonal theory that they are wrong. The water famine in Bombay and the general deficiency of the last rainfall in Western India may be put down as assisting the present outbreak in that city, but against such a deduction is the fact that the three previous attacks have not been accompanied by such deficiency and that it does not apply to other places.

A telegram from Colombo, dated Jan. 31st, states that plague has broken out in Adelaide, causing a tremendous scare throughout Australia.

Few people at home realise the extent of the famine which is at present existing in several parts of India. In consequence, however, of the admirable arrangements made for relief the distress is nothing compared with that of former times. In the British Provinces 2,694,096 persons were in receipt of relief last week, chiefly in the Bombay Presidency and the Central Provinces. In the Native States 788,512 were under relief, chiefly in the Native States in Rajputana, Central India, and Bombay. The greatest distress seems to prevail in the Central Provinces where nearly one and a half millions of people are under relief.

As some doubt has been thrown on the physique of the Volunteers proceeding from England to the seat of war it will be of interest to know that "Lumsden's Horse" now being formed in India consists of a very fine body of men. A large proportion are planters well accustomed to the saddle and the gun, who are of robust constitution and possess great physical powers. Leading an open life they are just the men to form an ideal regiment for the work in hand. These qualities, coupled with high spirits, energy, and great enthusiasm, complete the requirements for such a force. I understand that they are well equipped in every respect.

Feb. 7th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

War Notes.

A MEETING was held at the Medical Institute on Feb. 26th for the purpose of forming a local auxiliary to the organisation in London for providing comforts for the men of the Royal Army Medical Corps now in South Africa. The objects of the association were explained and subscriptions invited, as well as contributions of flannel shirts, socks, sleeping helmets, &c. Various officers were appointed and the hope was expressed that the results would be worthy of the profession in the Midland centre.—The students of Mason University College have made application to the War Office for permission to establish a Volunteer corps. It is proposed to form an additional company to the 1st Volunteer Battalion of the Royal Warwickshire Regiment, the membership being restricted to students. Over 90 names have been sent in and much enthusiasm has been exhibited. If the sanction of the War Office is obtained it is expected that the new corps will be in an efficient condition by the opening of the first term of the Birmingham University in October next.

The Fight with Tubercle.

Sir James Crichton Browne lectured to the members of the Midland Institute at Birmingham on Feb. 26th, taking the above title as his subject He advocated muscular exercise and stated his approval of military training for this purpose. Tubercle in milk, meat, and food was discussed and the vitality of bacteria was pointed out. The necessity for clean and dry dwellings, wider streets, and the purification of the slums was insisted upon with much eloquence.

Feb. 27th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Joint Parochial Hospital for Tuberculosis.

THE select vestry at their recent meeting discussed the draft order of the Local Government Board referred to in THE LANCET of Feb. 24th regarding the erection of a joint hospital for the treatment of tuberculosis by the select vestry and the West Derby and Toxteth boards of guardians, and it was practically decided to withdraw from the provisional arrangement which had been entered into with those two boards. The spirit of irresolution displayed by the select vestry in the matter of the proposed joint hospital has been a source of perplexity and irritation to the West Derby and Toxteth boards of guardians who, I understand, have announced their determination to proceed with the erection of a joint hospital independently of the select vestry.

The Liverpool School of Tropical Diseases.

The committee of the Liverpool School of Tropical Diseases have arranged to despatch a new expedition to the West Coast of Africa which will proceed up the river Niger and investigate further Major R. Ross's theory of the transmission of malarial fever by means of the mosquito. The *personnel* of the expedition has not yet been finally decided upon, but it will be composed of gentlemen who have devoted much attention to the question. The expedition will start at the end of March. Mr. Alfred L. Jones, the chairman of the school, has again kindly placed great facilities for travel at the disposal of the committee.

The Liverpool Eye and Ear Infirmary.

The eightieth annual report of the Eye and Ear Infirmary showed that 753 patients occupied beds last year compared with 709 during the previous year. 582 important operations were performed, as against 576 in 1898. In the out-patient department there were 5879 new eye cases and 2010 new ear cases. These have been attended to and prescribed for 20,054 and 6934 times respectively. The debit balance at the close of the year stood at £368 12*s.* 1*d.* and it would have been further increased but for the timely legacy of £250 from a deceased subscriber. The committee are indebted to the Hospital Saturday and Sunday Fund for the sum of £504. The committee regret that they are obliged to treat both legacies and donations as annual income, instead of paying off the balance of the mortgage debt of £1000, and creating a reserve fund, but at present they have no alternative. The decision of the corporation in regard to the payment of rates has added to the yearly expenditure of the hospital. The committee announced that Mr. Hugh E. Jones, who had filled the position of house surgeon and assistant surgeon, had now become an honorary surgeon. Allusion was made in a former issue of THE LANCET[1] to the change in the by-laws, at the instance of the committee, prolonging the term of office of the honorary surgeons to the age of 60 years and also giving privileges to the assistant surgeons after a term of years' service. No allusion has been made in the annual report to this important change. It was to be expected that the managers of the charity would have informed the subscribers at the annual meeting of these alterations of the by-laws, which, possibly, may require their sanction.

Extension of the Stanley Hospital.

The new out-patient department to which reference was made in THE LANCET of Feb. 24th was opened on Feb. 22nd by the Lord Mayor, in the presence of a numer gathering of ladies and gentlemen. At the conclusion of meeting the Lord Mayor handed to the treasurer a cheque £50 to be devoted to the needs of the hospital, so much to be deducted from the amount as would make his daughter a life governor of the institution.

Feb. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Professorship of Practice of Medicine in Edinburgh.

THE following are the candidates for this position: Dr. John Wyllie, Dr. Byrom Bramwell, Dr. Alexander James, and Dr. G. A. Gibson. Other names have been mentioned, but these gentlemen, it is understood, are the only persons openly in the field. The appointment will be made in April.

Scottish South African Hospital.

At a meeting of a sub-committee of the Scottish South African Hospital held on Feb. 23rd in Edinburgh in the City Chambers it was recommended that Professor Chiene should be appointed to act as head of the hospital and that Mr. David Wallace should be appointed as second in command to Professor Chiene; also that the four assistant surgeons should be Dr. C. M. Cooper, Dr. A. H. Watt, Dr. G. L. Chiene, and Dr. James Miller. It was also recommended that Miss Beveridge, matron of the Longmore Hospital, should be appointed as matron of the South African Hospital. Sir J. R. Andrew Clark, late Surgeon-Major A.M S., who will accompany the hospital to South Africa as the representative of the Army Medical Department is arranging matters of detail with Professor Chiene.

Lecture on Bacteriology.

On Feb. 20th Dr. Klein, lecturer on General Anatomy and and Physiology at St. Bartholomew's Hospital Medical School, delivered a lecture in connexion with the Edinburgh Philosophical Institute on "Bacteriology: its Aim and Object."

Epidemic of Influenza in Edinburgh.

At a meeting of the Public Health Committee of Edinburgh Town Council held on Feb. 20th Sir Henry Littlejohn presented a report on the present epidemic of influenza in the city. Since the beginning of January there had been 82 deaths in Edinburgh due to influenza or its complications. Of this number 41 deaths occurred in January and 41 since the beginning of February. There was thus an increase in the death-rate from influenza. Moreover, the disease, which originally appeared to be confined to the districts of Morningside and Grange, had now spread to other parts of the city. The deaths from influenza this year show a marked increase over the number which occurred as the result of the disease in 1892.

Feb 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

THE committee appointed to inquire into the causes of the high death-rate of Dublin continue to meet each day in the City Hall. A large amount of information has been gathered from the crowd of witnesses examined, but nothing new or startling has transpired. Some interesting evidence was given on Feb. 26th by Dr. E. W. Hope, the medical officer of health of the city and port of Liverpool, and by Dr. W. R. Smith, the medical officer of health of Woolwich, London, both of whom made instructive comparisons between the state of things in Dublin and that which prevails in Liverpool and in London. Dr. Hope stated that the tenement houses in Liverpool were very much smaller than those in Dublin and were in a far better condition as regards sanitation. He looked upon the closet accommodation in the Dublin houses as "extremely bad." In Liverpool they had 35,000 people living in insanitary houses, but there appeared to be far more in Dublin. In the witness's opinion, in order to put Dublin on fair terms for the purpose of comparison with English towns they should include the surrounding townships. If the city proper was considered without its natural extensions it should be compared with the central and more insanitary portions of English towns. In reply to Alderman Meade Dr. Hope stated that he did not know of a single city similarly circumstanced to Dublin, where the better classes lived outside and the poor lived in the centre; in fact, there was not a single one. On the question of the Notification of Infectious Diseases Act the witness stated that it was a matter of the greatest astonishment to him to learn that it was imperfectly carried out in Dublin, and that in some of the neighbouring townships which were geographically a continuation of Dublin it was not in force at all. He stated that in Liverpool it had never been necessary to prosecute a medical man for non-observance of the provisions of the Act. In fact, he did not know what they could have done there without the invaluable coöperation of the medical profession. Dr. Hope stated that he wished to say this with the greatest publicity and the greatest emphasis. On this question of the notification of infectious diseases, while agreeing with the general evidence of the last witness, Dr. W. R. Smith was no less emphatic; he thought it was most unfair to the sanitary authority that the Public Health Department were not presented with full information as to the presence of disease within their midst.

---

[1] THE LANCET April 15th, 1899, p. 1057.

The New Registrar-General for Ireland.

Mr. Robert Edwin Matheson has been appointed by the Lord Lieutenant Registrar-General for Ireland in succession to the late Dr. T. W. Grimshaw. Mr. Matheson has been connected with the staff of the Registrar General's office since 1865, and is, of course, more than familiar with the practical work of the department. He has been a member of the Irish Bar since 1875 and has filled the position of secretary to the Registration Office for many years. He has, moreover, held the responsible post of assistant registrar-general since 1879, acting as skilled assistant and legal adviser to the late Dr. Grimshaw. Mr. Matheson is the author of many works dealing with legal and statistical matters, and he is recognised on all hands as a man of marked ability in the special province to which he has devoted himself. It is worthy of remark that he was one of the Census Commissioners in 1881 and in 1891 and that he will have an opportunity next year, when the general census takes place, of again giving his valuable services to the public in connexion with that important statistical work. There are obvious reasons why the post of registrar-general should if possible be held by a physician, but in the absence of any medical candidate highly qualified for the position Mr. Matheson's appointment has given general satisfaction.

The Belfast Workhouse.

The half-yearly report of the Local Government Board inspector (Mr. Agnew) on the workhouse at Belfast has just been made public. He says that the Union Children's Hospital has twice the proper number of inmates for the available air-space, and he considers its position to be unsuitable. He reports that the quality of the beef supplied to the institution is inferior and he says that the number of the nursing staff is still under the required standard, the night nursing staff in particular being very insufficient. Further, in contravention of the Local Government Board's order, 62 healthy paupers are employed as attendants on the sick by day and 22 by night. Mr. Agnew reports that large numbers of the inmates classified as infirm men would not only be able to work but would be healthier and happier if they were employed at some light occupation. He thinks that stone-breaking, oakum-picking, and wood-chopping should be engaged in, and that a severe labour test should be applied to the large number of healthy inmates in the Belfast Workhouse. The Local Government Board request the guardians to take this important question into their careful consideration. It is really preposterous that, in a city like Belfast, where, owing to the large number of industries, everyone who is able and willing to work can get employment, taxpayers should be saddled with the support of healthy lazy paupers who find the Belfast workhouse a most agreeable hotel. Mr. Agnew's report has been referred by the guardians to sub-committees for further consideration.

The Adulteration of Milk in Belfast.

Several contractors to the Belfast Workhouse have been heavily fined for the adulteration of the milk-supply with water. The resident magistrates are determined to put down the practice and have inflicted fines of £50, as smaller amounts do not seem to produce any effect.

The South Charitable Infirmary, Cork.

The constitution of the Board of Governors of the Cork South Charitable Infirmary has been completely altered by the new Local Government Act. The board now consists of 29 members. The subscribers send 12 representatives, the county council nine, and the city council eight. The new board has issued its first annual report, containing some interesting items, from which it appears that the subscriptions represent a third of the total income, and that the expenditure exceeded the receipts by £107. There were 11,011 attendances in the extern departments. The daily average of intern patients, which was the highest for many years, was 77 as against 74 for 1898. The total number of intern patients was 1108. During the year the electric light had been installed at a cost of £101. Through the munificence of the Countess Murphy a very handsome chapel had been erected for the use of the Roman Catholic patients. The board recorded with regret the death of Dr. W. O. Townsend who had been consulting physician and had given 40 years' "faithful service to the institution, being esteemed as a painstaking and earnest member of the staff...... The unselfish devotion of the medical staff is ever a gratification to the governors whose confidence and goodwill they fully enjoy in the discharge of their onerous duties." The medical and surgical report recorded that although the most formidable surgical operations were performed the death-rate was only 2 per cent.

Feb. 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever in Paris.

TYPHOID fever is the universal subject of conversation at this moment in Paris. A number of cases, of which four have ended fatally, have occurred in a *lycée* and the Minister of Education has given orders for all the pupils to be sent home. This order has given rise to much public discussion in the press and elsewhere. Another *lycée*, situated in a totally different quarter, was also said to be infected, but the report was false, for the only cases of illness which have occurred are some of influenza. Taking advantage of the public interest in the matter Dr. Thoinot read a paper before the Academy of Medicine which has been a great deal talked about. At present he said there was nothing like an epidemic, properly so-called, of typhoid fever in Paris; at all events, the death-rate from the disease is not to be compared with that of last year, but the statistics certainly show a lamentable increase in the complaint. In 1895 the number of cases notified to the Prefecture of Police was 1389, in 1896 it was 1243, in 1897 it was 1342, in 1898 it was 1288, and in 1899 the number ran up to 4329. The number of deaths, which was 700 in 1894 (the last year in which there was a real epidemic), was 270 in 1895, 260 in 1896, 250 in 1897, 255 in 1898, and 754 in 1899. These figures are not relatively large if the population of Paris be taken into consideration, but they are much too high considering the sacrifices which the city of Paris has made to ensure that all the water used for alimentary purposes should be spring water and that proper drainage facilities should be insured. Dr. Thoinot considers that it is obvious that each new case arises from some contamination either in the water-pipes, the reservoirs, or the gathering grounds. In this connexion he refers to the remarkable researches of M. Martel who has for the first time made a complete study of underground water-courses, and who has, in fact, created a new science called "*spéléologie*." Dr. Thoinot has made a study of the various sources of the water taken up by the city of Paris for its drinking-water supply and comes to the conclusion that there is no trust to be placed in those sources of origin called "*vauclusiennes*"—that is to say, those in which the water traverses chalk beds and reappears on the surface after a long course underground but does not undergo filtration. There is special danger in those cases where the population around the head-waters have defiled them in any way. This state of of matters is to be found in a great number of Parisian sources of water supply. Dr. Thoinot pointed out that the headwaters of the Avre lie in an uninhabited country and that the quarters of Paris deriving their supply from this source have escaped the typhoid infection, while those deriving their supply from the Vanne have exhibited a high death-rate. The remedy is simple; the most complete precautions must be taken to prevent contamination of the head-waters or their tributaries and accurate chemical and biological examinations should be made. If any source of contamination is recognised the gathering ground must be removed to a point above it.

The French Edition of the "Index Medicus."

Last week there occurred in Paris an event the interest of which extends far beyond the frontiers of France—namely, the appearance of the first number (that for January, 1900) of *Bibliographia Medica* a work which it is intended shall carry on in Europe the traditions of the *Index Medicus*, the well-known publication of American bibliographers which was formerly published at Washington but ceased some six months ago. For the first time, not in France alone but also in Vienna and Berlin, there has been set on foot a bibliographical review comparable to the great work of Flechter and Billings, while it may even be adduced that the present work is superior in one way—namely, in the system of classification adopted. This great effort could not have met with success but through the International Institute of Scientific Bibliography at Paris, of which the director is Dr. Marcel Baudouin, the well-known journalist. The January number, which appeared on Feb. 15th, contains the greater part of the international bibliography of the medical sciences for January, 1900, and such a complete *tour de force* of editing and printing could not have been carried through except by using a staff of more than 150 persons who are employed in the press of the Institute of Bibliography at Paris. The new publication, which will deal with the whole of the international bibliography of the medical sciences, is founded on principles analogous to those of the American *Index Medicus* and will carry on the remarkable scientific traditions of that work which was so valuable. Thanks to the directors, Dr. C. Potain, member of the Institute and professor of the Faculty of Medicine at Paris, and Dr. Charles Richet, who is also a professor, notable improvements have been made in the editing and in the classifying of the subjects—which last is now practically perfect, so that search for any particular subject is rendered easy and rapid. The work, which will be issued monthly, as was the *Index Medicus* will contain some 4000 references per number of 80 pages at least, so that the number of references for the year will be about 50,000. The editors contemplate issuing special bibliographies as yearly and not monthly publications. These numbers, of which only a few copies will be issued, will be published by subscription. All the most modern methods of typography will be employed and the composition will be done by a machine, a method which offers great advantages for certain kinds of printing, but should occasion arise no extra expense will be spared. The annual subscription will be 50 francs a year for France and 60 for foreign countries, in place of 125 francs which was the subscription for the last American edition.

Feb. 27th

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Strophanthus as a Sedative.

DR. FEILCHENFELD writing to the *Centralblatt fur Chirurgie* recommends the administration of tincture of strophanthus previously to the production of anæsthesia by chloroform, as pre-anæsthetic excitement is thereby avoided. This is the case not only in cardiac failure but also in neurasthenic patients who are very much afraid of undergoing an operation. He gives five drops of tincture of strophanthus on two evenings and on the morning before the operation. Strophanthus is preferable to the bromide of potassium commonly used in these cases.

Collective Investigation on Carcinoma.

On the invitation of Professor von Leyden a committee lately met in Berlin in order to arrange a great collective investigation on carcinoma. The committee, which is still in process of formation and will be augmented by other members, included representatives of the Imperial Health Office, the Government Medical Department, and the Statistical Office. Professor von Leyden was elected chairman and Dr. George Meyer and Dr. Kirchner were elected secretaries.

A Radical Cure for Erysipelas.

A curious case is reported by Dr. Mosbacher of Bochum in the *Munchener Medicinische Wochenschrift*. He was consulted by a workman for erysipelas of the face and prescribed an ointment of 10 per cent. ichthyol. The next morning the wife of the patient (a Pole) came to Dr. Mosbacher complaining that the medicine had produced such severe diarrhœa and colic that her husband was unable to persevere with it. Dr. Mosbacher, greatly astonished, went to the house and found that instead of using the ointment in the ordinary way the man had taken it by the mouth. The erysipelas had nearly disappeared and the patient in broken German expressed his gratitude for the somewhat strong but very efficacious medicine which had done him so much good. Dr. Mosbacher adds that notwithstanding this success he has refrained from administering ichthyol internally.

Medical Congresses.

The Congress of Internal Medicine will, as you have already announced, meet this year in Wiesbaden under the presidency of Professor von Jaksch of Prague. The principal subjects to be discussed are: the Treatment of Pneumonia (introduced by Professor Korányi of Budapest and Professor Pel of Amsterdam) and Endocarditis (introduced by Professor Litten of Berlin).—The meeting of the Balneological Society will be held from March 8th to 13th at Frankfort. Professor Winternitz will read a paper on Phototherapy, Professor Schott of Nauheim on the Treatment of Diabetic Diseases of the Heart, Dr. Groedel of Nauheim on the Balneological Treatment of Diseases of the Kidney, Dr. Pariser of Homburg on Chronic Nervous Diarrhœa, Professor Kisch of Marienbad on Cardiac Complaints consecutive to Diseases of the Uterus, and Dr. Abbée of Nauheim on Arterio-sclerosis and Angina Pectoris.—The Surgical Congress will meet as usual in Berlin in the week following Easter, Professor von Bergmann of Berlin in the chair. Professor Czerny will read a paper on the Treatment of Unoperable Carcinoma, Professor Krönlein on the Results of Operations for Carcinoma of the Intestines, Professor Rehn on Resection of the Anus, Professor Israel on Operations for Renal and Ureteral Calculi, and Professor Augerer on Operations for Abdominal Contusions.—The German Committee for the International Medical Congress at Paris has been formed. Professor Virchow will be the chairman, Dr. Posner and Dr. Eulenburg will be the secretaries, and Dr. Bartels will be the treasurer. The other members are Dr. Aub of Munich (President of the Practitioners' Association), Professor von Bergmann of Berlin, Professor von Bruns of Tübingen, Dr. von Coler (general-staff-surgeon of the army), Dr. Curschmann of Leipsic, Professor Erb of Heidelberg, Dr. Ewald of Berlin, Dr. Leut of Cologne (President of the Committee of Medical Chambers), Professor von Leyden, Professor Liebreich and Professor Waldeyer of Berlin, Professor Ziemssen of Munich, and others.

The late Professor Meyer.

Dr. Ludwig Meyer, professor of psychiatry and director of the University Lunatic Asylum at Göttingen, died in that city on Feb. 8th. Professor Meyer, who was born in 1826, was one of the leading specialists for mental diseases and was the founder of the modern treatment of lunatics in Germany. After holding the appointment of assistant physician to the lunatic department of the Charité Hospital in Berlin he went from there to Hamburg as chief physician to the lunatic department at the General Hospital. He was one of the earliest and most fervent advocates of the non-restraint system in Germany, and very soon after entering on his Hamburg appointment he sold by public auction all the appliances previously used for the restraint of lunatics. He also allowed free visiting of the lunatics by their friends, just as in the case of patients of other classes. It was under his auspices that the great asylum at Friedrichsberg, near Hamburg, was established and at a later period the asylum at Göttingen, where he was appointed professor. He held that a modern asylum ought to be built according to the principles of a hospital and not of a gaol. Apart from his labours on behalf of the insane he did much work in the pathology of mental diseases and in conjunction with the late Professor Griesinger he edited the *Archiv für Psychiatrie*

The late Professor Leichtenstern

Professor Leichtenstern, the chief physician to the Cologne General Hospital, died from influenza on Feb 23rd Though not on the staff of a university he did much work in his special branch, internal medicine His principal subject was the ankylostomum duodenale which he was the first to observe in Germany He published numerous articles in the medical journals on the antitoxin treatment of diphtheria, on tuberculin, on cerebro spinal meningitis, and many other topics He was co editor of Ziemssen's Handbooks of General and Special Therapy and of Gerhard's Handbook of the Diseases of Children Professor Leichtenstern was the most distinguished consultant in Cologne

(FROM OUR OWN CORRESPONDENT)

Alive under the Coffin Lid

I MAKE no apology for returning to this ghastly theme The tragic "case in point reported in THE LANCET of Feb 24th from Lecce (Apulia) has thrilled the kingdom with horror "from the Alps to Etna'—horror shared by the foreign resident who may, as the result of illness, be equally the victim of Italian usage which makes burial follow so closely on death, real or apparent Popular interest in the theme is now accentuated by indignation, combined with panic, and increased vigilance over the circumstances intervening between the death certificate and the offices of the undertaker is leading to the discovery of cases only less gruesome than that of the Apulian peasant woman The latest of these comes from no less a quarter than the Ligurian Riviera, that lovely stretch of coast indented with sun traps of which Genoa and Spezia are the chief towns In the village of Roccabruna near Porto Maurizio an old countryman, Raffaele Rainoldi by name, fell ill, failed to recover, was certified as dead, and was laid in the coffin, with the despatch characteristic of Italian use and wont on such occasions The lid over him was actually being screwed down when he was felt to move and then heard to speak Medical aid was at once invoked by the family, half beside itself with mingled joy, surprise, and horror, and, thanks to restoratives skilfully applied the old man came round, recovered full consciousness and inspired hopes of his recovery These, however, were not realised He lingered for two days and then died death being this time not "apparent' but real Coincident with the chronicling of these cases the lay press is opening its columns to the discussion of the familiar devices—some of which are actually in force in mortuary chapels on both sides of the Alps—by which the individual laid out as dead and even enclosed in the coffin can still have air to breathe and the power to attract notice and assistance But none of these methods are of other than doubtful efficacy—the apparatus, for one thing, being too delicate and complicated not to get easily unworkable A better "device would be the insistence on a reasonable interval—such as prevails in England—between the death certificate and burial or cremation, and also on a more careful and less haphazard examination of the "dead" before certifying him as such

The Crusade against Tuberculosis

All the omens augur favourably for the success of the "Congresso contro la Tubercolosi to be held at Naples between April 25th and 28th next In the first place, there is a widespread intelligent, and even enthusiastic public sympathy with its object This feeling is fostered by the Government, which through the Minister of the Interior has announced a competition open to all the engineers of Italy, for the best plan for a sanatorium designed for the tuberculous poor The competitors must lodge their plans at the Ministry of the Interior not later than April 30th, 1900 at 12 o clock noon, and the author of the "first best' plan will receive 5000 lire (£200) and the author of the second best 3000 lire (£120) Again, as to the Congress itself, no effort has been spared to render it a worthy sequel to its predecessors held at Paris and Berlin Queen Margherita is its "high patroness" and the Minister of Public Instruction is its president Its organising committee, presided over by Dr Enrico De Renzi, Professor of Clinical Medicine in the University of Naples, includes some of the most authoritative names in Italy Its programme, finally, of which I have been favoured with an early copy, attests the care with which the whole subject has been surveyed and its discussion apportioned among those best fitted to undertake it The Congress will consist of four sections, the first dealing with Etiology and Prophylaxis, having the Rector Magnificus of Padua (Dr De Giovanni) as president, with such men as Murri of Bologna, Celli of Rome, Manfredi of Naples, and others hardly less distinguished to assist him The second section takes up the pathological and clinical side of the subject and is appropriately presided over by Professor Maragliano of Genoa, also adequately reinforced by no less authorities than Grocco of Florence, Bizzozzero of Turin, Marchiafava of Rome and Senise of Naples The third section devotes itself to Therapeutics and has for its president Professor E De Renzi, who will have as assessors Queirolo of Pisa, Cervello of Palermo, and Galvagni of Modena The fourth section deals with Sanatoria and its president is Professor D Capozzi of Naples, also worthily supported by men like Forlanini of Turin, Rummo of Palermo, Carlo Fedeli of Pisa, and others of "light and leading" in that *métier* All physicians, nature students, sanitary engineers, promoters of public hygiene, and social philanthropists will be welcome at the Congress, and have only indeed to send in their names to the "Segreteria del Comitato, nella Prima Clinica Medica, Ospedale di Gesù e Maria, Naples," *whence they will receive* a ticket of admission, price 20fr, which entitles them to the "Atti" and other publications of the Congress, to reductions in the railway and steamboat fares, to the trips to Pompeii, the Gulf of Naples and Palermo, and to all the privileges open to the "Congressisti,' Italian and foreign In connexion with the Congress the magnificent "Esposizione d Igiene,' under the patronage of the Prince of Naples, will also be open—a collection unrivalled I believe, in richness and variety, representing the high water mark of modern hygienic resource

Feb 27th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Department of Agriculture on the Production of Milk.

MAJOR ALVORD chief of the dairy division of the Bureau of Animal Industry, Washington, states that since July, 1895, there has been a dairy division under his care, the function of which is to acquire and disseminate information useful to dairymen Up to this time there has been but little surplus dairy products in the United States with the exception of cheese, but the prospect of a greater surplus in the future being good this division has been looking for foreign markets It proposes to make a good display at the Paris Exposition this year The first attempt to count the cows in the United States was made in 1840, and though this attempt has been made at each decennial census no approximate total has been received A great effort will be made at the next census to make a fairly accurate count It is probable that there are from five to five and a half millions of cows kept in the States for the purpose of producing milk for food, or about one cow to every 14 persons of all ages Milk is better handled now than it was a few years ago, especially in the matter of transportation and distribution; and milk has improved as to quality, as shown by the proportion of butter fat and total solids and its greater freedom from bacterial contamination This improvement is attributed to individual dairymen and companies rather than to legislation There has been some unnecessary alarm concerning the danger of milk as a food A careful study of the milk supply of the United States as a whole has convinced Major Alvord that the actual *presence* of disease germs in such milk supply is very rare and that the cases of real injury from these germs are rarer still, most of the evidence on this subject is negative and in favour of milk rather than against it It is generally conceded that the adding of preservatives to milk is most undesirable, as the process puts a premium on carelessness and dishonesty. Major Alvord affirms that he is strongly disposed to make the *same statement* regarding sterilisation and Pasteurisation, these methods may be employed on occasions but never as a rule. He would advocate at the present time the use of pure natural milk as being far better than all other preparations of milk as food. As to the value of skimmed milk as a food, he remarks that 100 pounds of skimmed milk contained more valuable food for the human being than 100 pounds of "whole" milk, and yet the sale of this article was prohibited in New York city because the city authorities had not felt like exerting themselves sufficiently to regulate properly a most desirable traffic. Skimmed milk was sold in Boston and very largely in the Connecticut Valley to the milk operatives, and the latter partook very largely of this product, greatly to their advantage. Another great inconsistency on the part of the authorities of New York city was that they freely admitted the sale of condensed skimmed milk but not of natural skimmed milk.

Women Nurses in Military Hospitals.

A Bill has been introduced into Congress to require the permanent employment of women nurses in army hospitals. It provides that there shall be a superintendent of women nurses, who shall be a woman graduated from a general hospital training school for nurses, having a course of instruction lasting not less than two years, who shall be appointed by the Secretary of War at a salary of $2000 per annum; that the nurses shall be graduates of general hospital training schools having courses of instruction lasting not less than two years; that they shall be appointed by the surgeon-general under regulations approved by the Secretary of War; that they shall receive $40 per month when on duty within the limits of the United States and $50 when on duty outside the limits of the United States.

The Losses of the Volunteer Troops in the Spanish-American War.

The Adjutant-General of the army has recently issued a statistical exhibit of strength of the volunteer forces called into service during the war with Spain, with losses from all causes. The total number of volunteers accounted for on muster rolls is 10,017 officers and 213,218 men enlisted; total, 223,235. Of officers, 18 were killed in action; 90 were wounded, of whom three died; 119 died from disease, four by accident, one by drowning, three by suicide. Of the men, 4544 were discharged for disability; 190 were killed in action; 1189 were wounded in action (78 of whom died from their wounds); 3729 died from disease, 97 by accident, 21 by drowning, 11 by suicide, and 30 by murder or homicide.[1] Among the officers mustered in were 1010 general and staff officers, including 143 belonging to the medical department of the volunteers. The only casualty among these medical officers was one death from disease. Of the staff officers three were killed, one belonging to the quartermasters' department, one to the subsistence department, one to the signal corps.

Progress of the Plague

In view of the progress of the bubonic plague, the United States Marine Hospital Service has taken measures to prevent its introduction into this country. 15 officers of this bureau have been detailed for service in foreign seaports, and three are already on duty at Cadiz, Barcelona, and Naples. The other officers are to be stationed at London, Liverpool, Southampton, Queenstown, Glasgow, Havre, Hamburg, Genoa, Antwerp, Rotterdam, Bremen, and Marseilles. These officers will inspect all vessels bound for the United States and keep the bureau informed as to the sanitary condition of the various cities.

Death-rates in Cities and States.

According to the recent records of the Marine Hospital Service the most unhealthy town in the United States was Liverpool, N.Y., with a death-rate per 1000 of 44 17, the population being 1200. Millerstown, Pa., with a population of 1162, reported only one death from any cause in 1898. Homestead, Pa., bears away the palm of healthiness; with a population of 10,000 there were 27 deaths in 12 months. Cleveland, Ohio, had a death-rate of 13 63; New York City, 19 28; Boston, 20 09; Baltimore, 19 10; Washington, 20 74; Chicago, 14·08; St. Louis, 14 28; and San Francisco, 19·41. The twin cities of Minneapolis and St. Paul had a death-rate of only 9 16 against that of New Orleans of 26·91. The most healthy conditions exist in the North-West and the region between the Mississippi river and the Rocky Mountains.

The New President of the New York State Medical Society.

At its recent meeting in Albany the Medical Society of the State of New York, U.S.A., elected to the presidency Dr. A. M. Phelps of New York City. The new President has been chosen from the surgical side of the profession and is a distinguished worker in orthopædics. He is a graduate of the University of Michigan, and is now professor of surgery in the University of Vermont (and professor of orthopædic surgery in the New York Post-Graduate School of Medicine.

The Physical Fitness of Railway Employés.

At a recent meeting of the New York State Association of Railway Surgeons the general claim agent of a western road stated that the last report of the Inter-state Commerce Commission informs us that there were 189,396 miles of railroad in this country and that 874,558 men were employed in the operation and maintenance of the same; that last year 489,444,189 passengers were carried and 741,705,946 tons of freight moved; that during the year 1898 there were 1958 employés killed, 31,761 injured, and 4680 other persons killed and 6176 injured. This frightful loss of life, together with the great loss of property, suggested that some standard of efficiency should be demanded form the employés. If a system of examination and the adoption of an age-limit were established the following benefits would be secured:—1. The company would secure the services of men who were physically capable of performing their duties properly and who would in all probability be able to do so for many years. 2. Men who were physically unfit for the work would be kept out of the service and the risk their employment would necessarily entail would be avoided; and at the same time the company would be protected from fraudulent claims for injury which this examination would detect. 3. The number of accidents and resulting expense would be reduced. 4. By reducing the number of accidents and making the business less dangerous a higher class of men would be encouraged to enter the service. 5. In case of injury it was well known that a sound man would get well quicker and make a better recovery than an infirm or diseased one, a fact which reduces the expense of adjusting his claim as well as the cost of caring for him.

Feb. 18th.

Obituary.

SAMUEL HYDE, M.D. ST. AND., M.R.C.S. ENG., L.R.C.P. EDIN.

By the death of Dr. Samuel Hyde, which occurred on Feb. 8th, Buxton loses one of her best known practitioners. Samuel Hyde was the son of Francis Hyde of Buxton, and entered King's College, London, as a medical student in 1872, when he was aged 21 years. In 1875 he obtained a Certificate of Honour in Obstetric Medicine, and qualified as a Member of the Royal College of Surgeons of England in 1877. He then started in practice at Buxton and for a considerable portion of the last 23 years was associated with the "Peak Hydro-Thermal" establishment. He devoted himself entirely to his practice and never took any part in the public affairs of the town. He was one of the original members of the British Balneological Society, was chairman of its council, and later became editor of the journal of the society. He wrote largely on the various subjects connected with balneology and was author of, amongst other works, "Buxton: its Baths and Climate," which reached a fourth edition in 1898; "Notes from Spa Practice," 1895; "The Therapeutic Value of the Buxton Waters," 1895; "The Causes and Treatment of Rheumatoid Arthritis," 1896; and "On the Uses of Animal Extracts in the Treatment of Chronic Joint Affections." Besides these he contributed various papers upon balneological subjects to the periodicals, among others an "Analysis of 200 Cases of Sciatica," which appeared in THE LANCET of May 9th, 1896. During the early part of last summer Dr. Hyde developed symptoms of intestinal trouble which, however, passed away. At the beginning of the winter, however, obstruction of the bowels gradually supervened, for the relief of which an inguinal colotomy was performed. The mischief was found to be malignant in nature and he gradually sank, dying on Feb 8th, aged 50 years He was buried in the cemetery at Burbage upon Feb 13th by the vicar of Buxton in the presence of a large number of friends He leaves a widow and one daughter

---

[1] "Murder or homicide" are the words which our correspondent has written, but how so many murders or homicides among the troops came about we are at a loss to guess.—ED. L.

JOSEPH WILLIAM YOUNG HOWISON LAVIES,
L F P S GLASG, M S A

THE death is announced from acute pneumonia of Mr J W Y H Lavies All old King's College men who were his contemporaries will sincerely grieve for his comparatively early decease, for he was one of the most popular men of his time during his career at King's College He was the son of a medical man, Dr J Lavies of St George's road, and after qualifying he settled down into practice and rapidly gained the affection and confidence of an increasing circle of patients But the rapid onset of pneumonia consequent on a chill caught a few days before led to his death at the early age of 46 years

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND —The following gentlemen passed the Preliminary Science Examination for the Licence in Dental Surgery, in Chemistry, Physics and Practical Chemistry —

Percy David Anderson and Hermann Bryan Victoria Science and Art Schools Southport George Stanley Bateman Birkbeck Institute William Bateman Dougan Owens College Manchester Frederic Neilhart Fox Municipal Schools of Science, Art, and Technology Gloucester Arthur William Gant Hymers College, Hull Wilfred Ernest Griffin Guy's Hospital William Richard Parker School of Science Technology and Art, Liverpool Ernest Harriman Tice and Stanley Arthur Tice, South West Polytechnic Institute Chelsea.

Eight gentlemen were referred to their studies for three months.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS —The following gentlemen having passed the necessary examinations have been admitted Diplomates in Public Health —

John Allison M D C M Edin F R C S Edin Edinburgh University Arthur Douglas Cowburn L R C P Lond M R C S Eng M D Brux University College Hospital Hugh Erushaw Finch, M B B Ch Oxon Oxford University and London Hospital Harry Percival Foulerton L R C P Lond., M R C S Eng St George's Hospital Shridhar Bheckajee Gadgil L M and S Bombay Grant Medical College Bombay and University College, London Harry William Henshaw L R C P Lond M R C S Eng St Bartholomew's Hospital John Newton Martin L R C P Lond M R C S Eng St Bartholomew's Hospital and University College London William Dunmore Murray M B C M Glasg Glasgow University and Jenner Institute Ernest Jackson Smyth L R C P Lond M R C S Eng M D B S Lond University College Hospital Alfred Spitteler M B, C M Medical College Madras and University College, London David Jones Thomas L R C P Lond M R C S Eng London Hospital; Robert Edwin Goonetilleke L R C P & S Edin M D Brux Ceylon Medical College Edinburgh University and Kings College London Frank Harris White L R C P Lond M R C S Eng, L S A Lond London Hospital

Three gentlemen were referred to their studies for six months.

SOCIETY OF APOTHECARIES OF LONDON —In February the following candidates passed in the subjects indicated —

Surgery —C B S Amos (Sections I and II) Royal Free Hospital C A W Egan Dublin and Charing-cross Hospital W J H Hepworth and O F Lemin (Section I) London Hospital R V A Mosley (Sections I and II) Leeds S Page (Section I), Birmingham A Y St Leger (Section I) Cambridge and St. Mary's Hospital N Walmisley St. Bartholomew's Hospital and A J Watson (Section I) St Mary's Hospital

Medicine —C B S Amos (Section II) Royal Free Hospital J F Hodgson Manchester J W H Morrison (Sections I and II) Durham R V A Mosley (Sections I and II) Leeds, and A C Oliver (Section I) Charing cross Hospital

Forensic Medicine —J F Hodgson Manchester, J W H Morrison Durham R V A Mosley Leeds and A C Oliver Charing Cross Hospital

Midwifery —W Alcock Sheffield C B C Chill, Charing Cross Hospital J I Halstead and J F Hodgson Manchester G J W Keigwin London Hospital A F Malaher St Thomas's Hospital R V A Mosley Leeds F A Q rke Birmingham; J O S Ral ligh St George's Hospital and M J Ryan St Bartholomew's Hospital

The diploma of the Society was granted to the following candidates entitling them to practise Medicine Surgery and Midwifery —C B S Amos C A W Egan W J H Hepworth R V A Mosley and N Walmisley

FOREIGN UNIVERSITY INTELLIGENCE —*Amsterdam* Dr J H Eberson has been recognised as *privat docent* of Diagnosis —*Berlin* Dr Julius von Michel, Professor of Ophthalmology in Wurzburg, has been offered and has accepted the posts of Director of the University Eye Clinic and Professor of Ophthalmology, in succession to Dr Schweigger, who is retiring at the close of the current winter session Dr von Michel was formerly assistant to Professor Horner in Zürich and subsequently taught ophthalmology both in Leipsic and Erlangen Dr Karl von den Steinen, formerly assistant to Professor Westphal in the Charité has been appointed Extraordinary Professor of Anthropology —*Copenhagen* Dr Reiss having attained the age of 70 years is retiring from the chair of Medicine —*Innsbruck* Dr H Malfatti has been appointed Extraordinary Professor of Medical Chemistry —*Lund* Dr J Borelius has been appointed Professor of Surgery —*Vienna* Dr Julius Neumann has been recognised as *privat docent* of Midwifery and Gynæcology

CITY ORTHOPÆDIC HOSPITAL —A series of lectures upon Elementary Anatomy and Physiology, Nursing (especially of Orthopædic cases), Application of Splints, Bandages, and Antiseptic Dressings, and Treatment of Patients Before and After Anæsthetics, &c, will be delivered weekly at the City Orthopædic Hospital, Hatton garden, E C, by Mr Noble Smith, Mr John Poland, Mr Chisholm Williams, Mr Jackson Clarke, and Mr Henry Davis The lectures will be given on every Tuesday from March to July inclusive at 5 30 P M, and will be free to all nurses

FESTIVAL DINNER OF THE SOCIETY FOR TRAINING TEACHERS OF THE DEAF AND FOR THE DIFFUSION OF THE GERMAN SYSTEM —In the absence of Lord Londonderry through illness, Lord Egerton of Tatton on Feb 21st took the chair at the festival dinner held by the Society for Training Teachers of the Deaf and for the Diffusion of the "German' (pure oral) System at the Hotel Cecil, Strand The society owes its bankers £3250, and a further sum of at least £15 000 is required to carry out a scheme of establishing a school for poor children to form adequate opportunity of practice to the students at the Training College The objects of the society are to train teachers on the pure oral system and to diffuse the knowledge of the system among parents of deaf children, educational authorities and the public The society has trained and certificated 113 teachers of the deaf, and these now compete with the school, so that the society has to fill its school mainly with children whose parents cannot afford fees that are remunerative In the course of the evening the secretary announced that £5300 had been subscribed After the usual loyal toasts the Chairman proposed the Army, Navy and Reserve Forces' Captain Philpotts, R N, M P, responded for the navy, Colonel Grubb for the army, and Captain Holt Stilwell for the reserve forces Viscount Duncannon, C B, proposed the "Houses of Parliament,' and was loudly cheered when he said that they would shortly have to discuss the future constitution of a great empire in South Africa Sir John Kennaway, Bart, M P, in responding to the toast of the "Houses of Parliament referred to the time when representatives of the British colonies will be seen at Westminster taking their share in the burden and direction of the great British empire The Chairman proposed the toast of the "Society for Training Teachers of the Deaf and for the Diffusion of the 'German' system,' and said that though other systems, such as the sign system and the combined, were much easier than the German system or, as he preferred to call it, the "pure oral system' the difference was very great Other systems precluded the deaf from becoming like other people, but what was wanted was to make the deaf as far as possible like other people and this was attained by teaching the pure oral system This system, however, had not spread widely because of the expense He understood that there was some contemplation of the foundation of scholarships by the county councils for the training of the deaf Dr Symes Thompson in replying to the toast, said that the pure oral system was based on true physiological principles and must be eventually accepted by the whole world It had been found necessary in the training school at Ealing to give special teaching in the anatomy and physiology of the organs of speech and hearing He described how the pupils were first taught to watch the lips of the teachers so as to be able to articulate letters and the process was then carried on into the construction of sentences Sir John Dorington Bart, M P, Mr Diggle Mr Soames, M P Sir Frederick Milner, Bart, M P, Mr B St John Ackers, and Mr Edward Bond, M P, also spoke

University of Cambridge.—The degree of Master of Arts is to be conferred on Mr Frederick Gowland Hopkins, B Sc., M.B. Lond., M.R C.S Eng., L.R C P. Lond., late demonstrator of physiology at Guy's Hospital, and now University lecturer in clinical physiology at Cambridge.—A prize of the value of £20 for the best M.D. thesis presented during the academical year by a graduate who has taken honours in arts has been founded by Mr. R. Horton-Smith, Q.C., in memory of his son. Raymond J. Horton-Smith was a scholar of St. John's College, and highly distinguished himself both at Cambridge and St. Thomas's Hospital. After taking the degrees of M.A. and M B. he died last autumn at the age of 27 years in the height of his brilliant promise.—The proposed agreement between the University and Addenbrooke's Hospital, which was approved by the Governors of the latter last January, is now offered by the Council of the Senate for adoption by the University. In consideration of an annual contribution of £300 the Governors will elect the Regius Professor of Physic and the Professor of Surgery to the staff, and will offer all reasonable facilities for clinical teaching examinations. An advisory council will also be appointed, on which the town, county, and University will each be represented by five governors. If, as seems probable, the arrangement is adopted certain difficulties of long standing between the two bodies will be happily removed.

Lunacy in New South Wales.—In the annual report for 1898 Dr. Eric Sinclair, Inspector-General of the Insane in New South Wales, states that the number of insane persons under official cognisance on Dec. 31st, 1898, was 4073, who were distributed as follows:—3901 (including 53 criminals) were in the seven hospitals for insane, 40 were in licensed houses, 123 were absent on leave under the provisions of the Lunacy Act, and nine were in hospitals for the insane in South Australia. The number on Dec. 31st, 1897, was 3957, so that the increase during the year was 116. The total increase for the 20 years beginning with 1879 was 2165, or an average of 108 a year. The estimated population of the colony being 1,346,240, the proportion of insane persons to the population was 1 in 330. The hospitals for the insane were overcrowded, and in view of this circumstance, as well as of the annual increase, Dr. Sinclair recommended the providing of additional accommodation. The statistical tables showed that 620 cases were admitted for the first time during the year, 110 were readmitted, 322 were discharged recovered, 39 were discharged relieved, and 246 died. Of the deaths, 21 were attributed to epilepsy and convulsions, 45 to general paralysis, and 27 to pulmonary consumption.

Vital Statistics of Queensland.—According to the annual report for 1898, issued by the Registrar-General of Queensland, the estimated population of the colony, on Dec. 31st, 1898, was 498,523, and was composed of 9989 Chinese, 8589 Pacific Islanders, 3269 Japanese, 358 Javanese, 2242 "other Asiatics," and 474,076 "all other nationalities." From this it will be seen that coloured aliens comprise less than 5 per cent. of the total population, of which the Chinese contribute just 2 per cent. The population of the city of Brisbane within the five-mile radius was 107,840. There were 2972 marriages celebrated in 1898, giving a marriage-rate of 6 03 per 1000. The Queensland marriage rate has been declining steadily since 1863, when it was 14·5 per 1000. The highest marriage-rate in the Australasian colonies during 1898 was in Western Australia, where it was 9 89 per 1000, as compared with 10 65 per 1000 in 1897. The oldest bride was 60 and the youngest was 15 years of age; in former years, however, there have been instances of brides aged 13 years. There were only 13,933 births registered during 1898, which was a smaller number than in any other year of the past decade, and gave a birth-rate of 28 3 per 1000. The relative number of illegitimate births has increased during the last two years; in 1894 the illegitimacy rate was 4 52 per 1000, in 1897 it was 6 02, and in 1898 it was 6 04. The deaths numbered 6243, comprising 3771 males and 2472 females, against 3483 males, 1940 females, and 5423 persons in 1897. The infant mortality, computed from the ratio of the number of deaths under one year to the number of births, was 11 05 for 1898, and the mean for the last decade was 10 61. In the classification of the causes of death the three most fatal diseases were phthisis, pneumonia, and enteritis, the proportion per 10,000 of total deaths assigned to them being respectively 674, 580, and 545. Cancer is found to be increasingly prevalent. Among the less usual causes of death nine fatal cases of caisson disease are recorded.

For the twenty-seventh time, at a meeting of the Rural District Council of the Eastern Division of the Corwen Union, Mr. James Pratchett Drinkwater, M.R.C.S. Eng., L.S.A., was elected medical officer of health.

Royal College of Surgeons in Ireland: Fellowship Examination.—Mr. D. A. Fitzgerald having passed the necessary examination has been admitted a Fellow of the College. The following gentlemen have passed the primary part of the examination: Mr. F. H. McC. C. Crawley, Mr. K. L. G. Gunn, Mr. S. H. Law, Mr. A. Charles, Mr. T. A. Dillon, and Mr. A. H. B. Hartford.

Presentation to a Medical Man.—Mr. J. P. Bush of Clifton Park, Clifton, Bristol, who has been appointed chief surgeon of the Princess Christian Hospital, shortly to leave for South Africa, was presented on Feb. 22nd by his friends, previously to going on active service, with a compact case of surgical instruments, the outer case being of silver and appropriately inscribed.

Queen Charlotte's Lying-in Hospital.—The Earl of Hardwicke presided at the annual meeting of governors of this hospital on Monday, Feb. 26th. The report stated that during the year 1150 patients had been delivered in the hospital and 1011 at their own homes. The committee were receiving into the hospital as patients the wives of soldiers and sailors on active service with the forces in South Africa. Nearly 50 of these women had been helped. The expenditure had amounted to £4390 7*s.* 9*d.* and the ordinary income to £3378 19*s.* 7*d.* The Prince of Wales's Fund had made a grant of £300 to the hospital and £50 to the convalescent home. The event of the year had been the opening of the new nurses' home by the Duke and Duchess of York in July last. The chairman, in moving the adoption of the report and accounts, made an urgent appeal for contributions towards the £5000 still needed for the work to the hospital and the new nurses' home.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

New Factory Legislation

The Home Secretary has made it known that his Bill for the amendment of the Factory Acts which he hopes shortly to introduce will provide new machinery for bringing into force the special rules applicable to dangerous trades, such, for instance, as the earthenware trade, and will also deal with the question of arbitration in connexion with which there has recently been so much difficulty.

The Medical Service of the Royal Navy.

In the statement of the First Lord of the Admiralty explanatory of the Navy Estimates for the year 1900-1901, reference is made to several changes which have been effected or are in contemplation in connexion with the medical service of the navy. It is announced that the numbers of Inspectors-General and Deputy Inspectors-General of Hospitals and Fleets have been increased and the conditions which are required for promotion to these ranks have been modified. The period of the course of instruction at Haslar Hospital for Surgeons on entry has been extended and the award of prizes at the end of each session introduced. The number of medical officers allowed to undergo periods of study at medical schools has been considerably increased and the privilege extended to the senior ranks. An additional professor has been appointed to the instructing staff at Haslar in connexion with the study of diseases of foreign stations. The last paragraph in the statement is perhaps the most important. It announces that medical officers newly entered will in future be required to provide themselves only with a pocket case of instruments as all ships bearing medical officers and naval and marine barracks will be supplied with surgical instruments at the public cost within the next three years. When Mr. Goschen came to introduce the Navy Estimates in the House of Commons he referred to some of these topics and gave the assurance that the Admiralty are doing what they can to give the medical officers in the navy greater opportunities for studying and informing themselves generally with reference to the progress of medical science, and also to relieve them of burdens which seem to the Admiralty to be unjust

HOUSE OF COMMONS

THURSDAY, FEB 22ND.

Enlistment for the Royal Army Medical Corps

Sir WALTER FOSTER asked the Under Secretary of State for War whether, seeing that no recruit could be enlisted for the Royal Army Medical Corps if he was over five feet five inches in height, however otherwise eligible he might be, this restriction which prevents enlistment of men otherwise eligible in that branch of the service could be removed.—Mr WYNDHAM The maximum standard for the Corps is five feet five inches but a taller man who might for special reasons be eligible would be taken as "specially enlisted."

Nursing Orderlies in South Africa

Sir WALTER FOSTER asked the Under Secretary of State for War if the number of nursing orderlies employed in field and general hospitals in South Africa was only one orderly for every seven patients, and if, in the interests of efficiency, it could be increased to one for five patients.—Mr WYNDHAM The proportion of orderlies to beds is as stated—*one to seven*—*and the Secretary of State is advised that that* is sufficient In a field hospital the bearer company can supply additional orderlies as soon as an action is over, and as patients are always transferred as soon as possible to the base hospital the beds are rarely all full In a general hospital many of the cases are always slight and there is a regular staff of nursing sisters

Netley Hospital.

Captain NORTON asked the Under Secretary of State for War whether it had been brought to his notice that the dining halls at the Royal Victoria Hospital, Netley, were supplied with wooden forms without any back support which were unsuitable for invalids, and if he would consider the advisability of substituting barrack chairs.—Mr WYNDHAM Not long since the opinions of Principal Medical Officers as to the requirements of military hospitals were collected and reported upon by a committee The change suggested was not among those proposed The question, will, however, be considered

Housing of the Working Classes

Mr. CHAPLIN introduced a Bill to amend Part III of the Housing of the Working Classes Act, 1890 He explained that the main provision of the measure was to enable local authorities to establish or acquire lodging houses for the working classes outside their respective districts and that further it simplified procedure under the Act.

FRIDAY, FEB 23RD

Plague and Famine in India

Lord GEORGE HAMILTON, replying to a question on this subject, said: The number of deaths in Bombay city from plague during the week ending Feb 16th was 683. The number for the corresponding week in the preceding year was 712 As regards the famine the latest estimate of the area affected is now 445 000 square miles and that of the population affected 61 500,000 as against 530,000 square miles and 49,000,000, which were the figures given by me in answer to a question on the 1st of this month The number of persons in receipt of relief is now about 4 000 000 as against 3 000 000 in the corresponding week of 1897 On the other hand the relief arrangements are more advanced than they were in 1897, the people are more ready to accept relief, prices are on the whole less high, and the death rates in the famine districts so far as yet known are lower,

Sanitary Inspectors

On the motion of Mr PERCY THORNTON a Bill was introduced and read a first time to amend the law as to the qualifications and tenure of office of sanitary inspectors and to make other relative provisions Among other things the Bill gives sanitary inspectors an appeal from their employers to the Local Government Board

The Purity of Water supplies

Mr. CORNWALLIS asked the President of the Local Government Board if he intended to introduce a Bill this session to safeguard to consumers the supply of drinking water by companies and others.—Mr CHAPLIN replied that he was preparing a Bill upon the subject and had every hope of introducing it

MONDAY FEB 26TH

Anti Enteric Vaccine

Mr POWELL WILLIAMS replying to a question addressed to him by Sir JAMES FERGUSSON, said that anti enteric vaccine is placed on board all transports proceeding to South Africa

The Anti Vivisectionists and Mr R. E Lloyd

Mr WEIR asked the Secretary of State for the Home Department if he would state how often within the last two years the Physiological Laboratory, University College London, had been visited by the Government Inspector, was he aware that Mr R E Lloyd, B Sc., in the *Journal of Physiology* dated Feb 2nd refers to experiments which he made upon three cats and four monkeys, the animals being allowed to linger for two months before death ensued would he ascertain whether these experiments were made without the use of anæsthetics, and, if they were, would he say when a certificate enabling Mr Lloyd to dispense with the use of anæsthetics was granted, and, whether any of these experiments were made in the presence of a Government inspector.—Sir MATTHEW WHITE RIDLEY The Physiological Laboratory at University College was visited by the Government inspector three times in 1898 and once in 1899 During the last quarter of 1899 no experimental work was being carried on there As regards the last three paragraphs of the question, I think the article in the *Journal of Physiology* has been misunderstood It does not appear that Mr Lloyd performed any experiments on living *animals at all and he refers in the* paper only, so far as his own work is concerned, to microscopical examination of some brains removed after death from animals upon which experiments had been previously made under anæsthetics by a person holding the proper certificates

The Care of the Teeth.

Mr WEIR asked the Vice-President of the Committee of Council on Education, having regard to the fact that a large percentage of the young men who enlist in Her Majesty's army are subsequently rejected on account of bad teeth, would he consider the expediency of arranging for a fully-qualified dentist to attend periodically at each school under the control of the Council for the purpose of inspecting the teeth of all lads over the age of 10 so that they may be encouraged to take such steps as are necessary for the preservation of their teeth.—Sir JOHN GORST: The Committee of Council regard this as a matter for the consideration of local authorities and managers of schools, but the suggestion of the hon member shall be considered.

TUESDAY, FEB 27TH

Civil Surgeons at the War

Sir WALTER FOSTER asked the Under-Secretary of State for War whether a supplementary list could be placed in the Army List of civil surgeons employed with the army in South Africa, and whether a list of the field hospitals, bearer companies, and general hospitals employed in South Africa, could be placed in the Army List after the medical officers in the Army List, showing the names of officers with each hospital or company.—Mr WYNDHAM It is not the practice to insert the names of civilians attached to the army in the Army List. It would be exceedingly inconvenient to do so seeing the temporary character of their engagement In regard to the proposal in the second paragraph, the changes constantly in progress following the disposition of the troops would render it quite impossible to keep such a statement up to date

WEDNESDAY, FEB 28TH

The Midwives Bill.

The second reading of the Midwives Bill, which stood as the second order at this sitting of the House, was not reached until after the time for the discussion of contested business and consequently, when formal objection was taken, the order was postponed If the objection be persisted in there will be little or no chance of any progress being made with the Bill this session Notice of a motion for the rejection of the measure has been given by Mr T P. O Connor.

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week, for publication in the next number.*

ALEXANDER, T. A., L R C P., L.R.C S Irel, has been re appointed Medical Officer for the Saham Toney Sanitary District of the Swaffham Union

ALLAN, C. M., M A, M D, M S Edin, has been appointed Public Vaccinator for the Longton District of the Stoke upon Trent Union, vice Alfred Averill

Pitts-Tucker—Le Doux.—On Feb. 24th, at St. Luke's, Redcliffe-square, Francis Augustus Pitts-Tucker, M.R.C.S., L.R.C.P. Lond., fourth son of Mr. T. J. Pitts-Tucker of Barnstaple, to Antoinette Augusta (Tony), third daughter of G. R. Le Doux of London.

DEATHS.

Duke.—On Feb 22nd, at Villa Albert, Cannes, Douglas William Duke, M.R.C.S., aged 51.

Scattergood.—On Feb 22nd, at Park square, Leeds, Thomas Scattergood, M.R.C.S., L.S.A., aged 74 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL CERTIFICATES FOR THE LONDON SCHOOL BOARD

WE have from time to time commented severely upon the discourteous attitude which the London School Board show, through its officials *towards the medical profession* We had thought that *owing to the* resolution passed on Jan. 21st, 1897 (THE LANCET, Jan. 30th, 1897, p 331), this discourtesy would cease But on Feb. 17th a member of the staff of the Royal Westminster Ophthalmic Hospital attended the South Western Police-court to express his dissatisfaction at the unnecessary demands of the School Board officers Mr Burton, the superintendent of the Lambeth Division, had summoned a man named Braby for not sending his child to school and it transpired that the child was under treatment at the hospital and that the surgeon had given a certificate to the effect that the child was unfit to attend school He had, however, not filled up one of the official school board certificates but the form in use at the hospital The School Board must remember that certificates are given not because the Board has any right to demand a certificate, for it has none, but purely out of courtesy and with a desire to save the child or its parents from a prosecution Secondly, the Board has no right to demand to know what is the nature of the illness from which a child is suffering It is quite sufficient that the child should be returned as unfit to attend school The nature of an illness, except in certain cases of an infectious kind, is a confidential matter between the medical man and his patient The magistrate agreed that the surgeon was quite within his rights in using only the hospital form He did not fine the parent of the boy and directed Mr Burton to withdraw the summons and *to take* out another if the boy did not attend school when able to do so Mr Sharpe once complained of the School Board having to undergo odium on account of such prosecutions As long as the Board disregards medical certificates it will be liable to such odium Instead of harassing the parents of children who are certified to be under medical treatment the Board would better employ its time in clearing the streets of small urchins who hawk newspapers and other things. Possibly this might bring a further rise in the rates, but that is a matter which never causes the Board the least uneasiness The medical man, in the particular case under consideration, deserves every credit for attending the court, and thanks are also due to the magistrate for his decision in the matter

WANTED, A HOME.

To the Editors of THE LANCET.

SIRS,—Could some of your readers tell me of a home where a girl, aged 20 years, of the servant class, suffering from melancholia, could be admitted as soon as possible? The father could pay from 6s to 10s. a week for her I am, Sirs, yours faithfully,

Feb 26th. T E, L R.O P & S

AN IMPROVED "ESMOND' CYCLE SADDLE

THE Esmond Cycle Saddle Company of Botolph House, Eastcheap, London, E C, have still further improved their "Esmond" saddle and the tests to which we have put it are highly satisfactory in their results In its old form the saddle had a backward and forward swing while it also partially rotated laterally These movements are still maintained but in addition the back of the saddle is now supported on two springs For travelling over rough ground and for climbing hills the saddle is one of the best we have tried while in all cases the usual discomforts are reduced to a minimum Not the least of the advantages of this saddle is the fact that if properly adjusted there cannot possibly be any "bumping" or slipping on the seat

THE ASSUMPTION OF MEDICAL TITLES

ON Feb 25th, Harry Edwin Collis of Cambridge street, Hyde Park, was summoned at the instance of the General Medical Council for wilfully and falsely pretending to be a Doctor of Medicine and for unlawfully using the titles "Doctor" and "M D" In November, 1899, the General Medical Council received from Keble College, Oxford, a pamphlet published from C bridge-street, Hyde Park. In consequence of this the defendant s premises were visited and on the door, the railings, and the letter box were found brass plates bearing the name "Dr Washington Evans" As this gentleman had been struck off the Register in 1885 the solicitors to the General Medical Council caused a letter to be written to "Dr Washington Evans, Cambridge-street." A letter was received in reply signed in the name of "Washington Evans" and mentioning terms for treatment This letter the defendant admitted was written by himself. The brass plates were removed after the summons was issued Mr Freke Palmer, for the defence, said that Dr Evans had died in November, 1899 and the widow had asked the defendant to carry on the business for her He did so entirely for her benefit. The business had now been stopped Mr Curtis Bennett is reported as saying that the worst feature of the case was that defendant had no qualifications for carrying on the business, and but for these proceedings he would probably still be conducting it. Defendant was fined 40s and five guineas costs Mr Collis may have been actuated by motives of pure humanity and anxiety to assist a widow, but this does not excuse fraud Personation of a dead man is a serious offence in any case, and when the personation necessarily entails an assumption of qualifications and knowledge which the personator does not possess the offence is doubly grave

"THE CLERGYMAN AND THE MEDICAL MAN."

WITH reference to the letter upon this subject which appeared in our columns on Feb 17th we see that our contemporary, the *Chemist and Druggist*, of Feb 17th, prints the "Sure and Certain Cure for Influenza" as it appears in a Glasgow paper It there reads as follows: "Pure Phenol Calvert's No. 1, prepared for internal use Dose: two tablespoonfuls in a wineglassful of water three times in 24 hours. ." An ounce of pure carbolic acid in an ounce of water would probably be fatal

"MEDICAL ATTENDANCE IN BOURNEMOUTH"

To the Editors of THE LANCET

SIRS —Having read "One of the Ailing's" complaint and your reply in THE LANCET of Feb. 24th I still think that reform is desirable in this matter As a resident in London it has often forced itself unpleasantly upon me that if after, say, 1 P M I required medical advice it was useless to visit a medical man on that day until the evening As I understand the matter they are to be consulted up till midday, after this they are either at hospitals or visiting their patients. As to hospitals, I suppose it would be difficult to vary the time of attendance, but surely some of the profession might visit patients in the morning and thus be available for consultations in the afternoon I am, Sirs, yours faithfully,

Feb 26th, 1900 A PATIENT

WHO IS TO PAY?

To the Editors of THE LANCET

SIRS,—I should like the benefit of your opinion in the following case I am sent for to attend a single girl of 18 years of age at her confinement I deliver with forceps and ultimately, at the girl's request, send in my bill of two guineas to the father who defies me and will not pay The girl, I may say, left her home and went to stay with some people in the next street and was delivered there She has remained with them ever since and has left for another town with them. The girl s father is, I am informed, in possession of a sum which was paid him by the father of the child I am told that I cannot successfully sue the girl s father and as the girl has nothing it would be useless to sue her The father says his house was open to her and that he did not want her to go anywhere else Can you advise me what to do? I am, Sirs, yours faithfully,

Feb 24th, 1900 DISPUTED ACCOUNT

*** We can only recommend our correspondent to employ a solicitor and follow his advice —ED L.

A CASE OF INTRACTABLE ULCER

To the Editors of THE LANCET.

SIRS,—I wish to gain the assistance of some of your readers in the following case. The patient is very debilitated and is suffering from an ulcer of about the size of a shilling situated on the inner side of the tibia The ulcer is the result of an injury and is of some three months' standing The patient has had eczema of the same leg which was very intractable. Iodoform ointment and dressings have been tried, but with little benefit It occurred to me to try the "Oxygen Treatment," but I should like to have the opinion of others before doing so and should be grateful for full particulars as to mode of application

I am, Sirs, yours faithfully,

TIBIA

*** The address of the Oxygen Home is 2, Fitzroy square, W, and full information will be given on application to the secretary.—ED L.

"DESCRIBED AS A DOCTOR."

THE *Morning Herald* of Thursday Feb. 15th contained the following paragraph —

> PERJURY BY A DOCTOR
>
> Lionel George Peyton Holmes, described as a doctor, pleaded guilty to an indictment charging him with having committed perjury in an action tried in the Mayor's Court, Guildhall —It was stated that Holmes gave evidence in an action tried recently in the *Mayor's Court, when he swore that he was a Licentiate of the* Society of Apothecaries and qualified to give medical advice He gave his name as George Holmes in which name, it appeared, that some time ago a certificate was issued, but, it was alleged, not to the accused.—Mr Overend on behalf of prisoner, stated that he had acted as a dispenser to medical men His present position meant a very serious thing to his future —The Common Serjeant passed a sentence of three months' imprisonment, as an offender in the Second Division

It is singularly unfair to head such a paragraph "Perjury by a

Doctor." The practice of calling any person who has dabbled in drugs or castrated cats a "doctor" is on a par with that which obtains of describing every rowdy street-walker as an "actress." Holmes's counsel stated his client's position, and the prisoner should have been described accordingly.

DIFFICULTIES UNDER THE VACCINATION ACT.

To the Editors of THE LANCET.

SIRS,—Can you advise me if anything can be done under the following circumstances? I find that the percentage of vaccinations I get to do are not what they should be, due to this fact—a local medical practitioner arranges to vaccinate any child in one place only for the sum of 1s.; he thus brings the public vaccinators into disrepute because they must do four places, and also he, I think, to a large extent invalidates the benefit of the Act. I may add that this has been going on for years, but has greatly increased since the New Vaccination Act came into force. I know that other public vaccinators around complain of the same thing. Can it not be stopped?

I am, Sirs, yours faithfully,

Feb. 17th, 1900. A P. V.

*** According to the instructions of the Local Government Board dated Jan. 7th, 1897, a public vaccinator must "in all ordinary cases of primary vaccination, make such insertions of lymph as will produce at least four separate good-sized vesicles, not less than half an inch from one another," and if these instructions are not carried out the public vaccinator would incur the risk of losing the Government grant, while if such instructions were habitually disregarded there might be question as to whether the vaccinator would be allowed to continue in office. We fear there is at present no remedy for the obviously unfair state of things referred to by our correspondent, and, moreover, the practice is likely to lead to the creation of a large and very imperfectly protected number of children. The moral responsibility of these practices rests with the medical men who condescend to employ them. Until "vaccination" is defined by law there is, we fear, no legal remedy. We shall, however, continue to condemn in our columns such apology for vaccination.—ED. L.

◆

M.P.S.—The matter is not referred to in the Medical Acts. There is a regulation of the General Medical Council to the effect that six months of the fifth year of study may be spent with a *registered practitioner*. The General Medical Council in November, 1897, agreed that notices relative to the employment of unqualified persons as assistants or otherwise should be inserted as an advertisement in the medical journals. (*See* THE LANCET, Dec. 11th, 1897, p 93 of the advertisement columns.) In this notice the Council pointed out that after a certain lapse of time any practitioner employing an unqualified assistant or "covering" should be deemed guilty of "*infamous conduct in a professional respect*," and added that the foregoing notices "do not apply so as to restrict the proper training and instruction of *bonâ-fide* medical students and pupils .. . under the immediate personal supervision of registered medical practitioners" The Council further decided that they "do not think it necessary or expedient .. ... to lay down regulations intended to meet all the particular cases which may arise. As in all other instances, the Council must deal with each case on its merits."

Hygiene.—Our correspondent is advised to consult, in addition to the books he mentions, Surgeon-Major A. M. Davies's "Handbook of Hygiene." London. Griffin and Co., price 12*s.* 6*d.* The articles on Climatology and on Plague and other *Infectious Diseases* in Allbutt's System of Medicine will also be found useful. The most recently published instructions upon plague were contained in a circular issued by the Local Government Board for Scotland dated Jan. 15th, 1900, upon which we commented in THE LANCET of Jan. 20th, p. 179.

X. Y. Z.—We cannot attempt to guess what view the General Medical Council may take when both sides of the question are placed before them.

R. I.—We have not the information. The reading room of the British Museum is not difficult of access.

Rural.—There is an excellent historical sketch in the "National Dictionary of Biography."

Mr. A. Cooper Fenn.—Our correspondent is thanked for his letter.

T T.—We have already made a reference to the case.

Singer should consult his medical man.

F.R.C.P. Ed.—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Norfolk Standard, Blackburn Telegraph, Bradford Observer, Sheffield Independent, Bristol Times and Mirror, Manchester Evening Chronicle, Manchester Courier, Brighton Gazette, Daily Gleaner* (*Kingston, Jamaica*), *Pioneer Mail, Times of India, Scotsman, Citizen, Builder, Architect, Sanitary Record, South Wales Daily News, Public Health Engineer, Birmingham Daily Post, Kentish Observer, Lincoln Echo, Liverpool Daily Post, Leeds Mercury, Hertfordshire Mercury, Bristol Mercury, Local Government Chronicle, Yorkshire Post, Reading Mercury, City Press, Teesdale Mercury, Scientific American, Dewsbury Reporter, Ripley Advertiser, Health, New Zealand Herald, Star, British Dental Journal, Morning Advertiser, Portsmouth Times, Surrey Advertiser, Local Government Journal, Mining Journal, Burnley Gazette, Essex County Standard, Australasian Medical Gazette, Weekly Free Press and Aberdeen Herald, Southwark Record, Isle of Wight Herald, Wakefield Herald, Lichfield Mercury, Gloucestershire Echo, Rangoon Gazette, Oban Times, Cork County Eagle, Birmingham Daily Post,* &c., &c.

Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M..

TUESDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.).

WEDNESDAY (7th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.)

THURSDAY (8th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.) University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.).

FRIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (10th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (5th).—MEDICAL SOCIETY OF LONDON.—9 P.M. Sir W. M. Banks: Practical Observations on Cancer of the Breast. (Lettsomian Lecture)

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.)—7 P.M. Council Meeting. 8 P.M. Communications:—Mr. B Neale: (1) A Case of Multiple Necrosis of the Mandible of Dental Origin, with Notes on the Surgical Aspect of the Case by Mr. F. Marsh; (2) Prophylactic Lower Dentures. Cases and Specimens will be shown by Mr. H. Baldwin, Mr. H. R. F. Brooks, and Mr. M. Henry.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish square, W.)—4.30 P.M. Cases and Specimens will be shown by Prof. U. Pritchard, Mr. R. Lake, Dr. H. Tilley, Mr. A. Cheatle, Mr. W. C. Bull, and Dr. J. Horne Adjourned Discussion on the Cases shown at the last meeting by Dr. D. Grant, Mr. A. Cheatle, and Mr. E. Waggett. Discussion of Cases and Specimens shown at the Meeting.

Society of Arts.—8 p.m. Mr. E. S Shepherd: Photography of Colour.

TUESDAY (6th).—Pathological Society of London (Laboratories of the Royal Colleges of Physician and Surgeons, Victoria Embankment, W.C.)—8.30 p.m. Papers and Demonstrations:—Dr. Brodie and Dr. Dixon: The Influence of Drugs on the Pulmonary Circulation and the Bronchial Muscles. The Production of Asthma.—Dr. Brodie: The Action of Diphtheria Toxin on the Spleen.—Dr. Pavy: The Production of Glycosuria by Exalted Respiration.—Dr. Pavy, Dr. Brodie, and Mr. Sian: Phloridzin Glycosuria in an Artificially Perfused Kidney.—Dr. Bain: Observations on Metabolism in Rheumatoid Arthritis.—Dr. Grube: The Pathology of Diabetic Coma.—Dr. Cadman: The Arrangement of Fibres in the Rootlets of the Ninth, Tenth, and Eleventh Cranial Nerves.

WEDNESDAY (7th).—Obstetrical Society of London.—8 p.m. Specimens will be shown by Mr. G. W. B Lawrence (introduced by Dr. Blacker) Dr. Macnaughton-Jones, and others. Demonstration:—Mr. A Keith (introduced by Dr. Lewers): Dropsical Parasitic Twin Fœtus of Peculiar Form. Paper:—Dr. J. Phillips: A Case of Extra-uterine Gestation in which Fœtal Death occurred at Term after Spurious Labour and Abdominal Section was performed from four to five months later.

THURSDAY (8th).—Ophthalmological Society of the United Kingdom.—8 p.m. Cases and Card Specimens. 8.30 p.m. Papers:—Mr. W. M. Beaumont: Family Tendency to Ophthalmoplegia Externa.—Mr. A. L. Silcock: Meningitis followed by Panophthalmitis.—Mr J. H. Fisher: Pigmented Tumour of the Eyeball, Death from Multiple Pigmented Carcinomata nearly 14 years after Excision of the Eye.—Mr. H. W. Dodd: Green Vision.—Mr. W. H. Jessop: Embolism of both Central Retinal Arteries.

Medical Society of London (Whitehall Rooms, Hotel Métropole).—7 p.m. Anniversary Dinner.

British Gynæcological Society (20, Hanover-square, W.).—Specimens will be shown by Mr. S. Bishop, Dr. G. Elder, and Dr. Macnaughton-Jones. Papers:—Dr. R Worrall: Pregnancy complicated with Myomata and Ovarian Cyst.—Dr. M. Laurie: The Indications for the Removal of the Uterine Appendages.

FRIDAY (9th).—Clinical Society of London (20, Hanover-square, W.).—8.30 p.m. Papers:—Dr. Caton: The Prevention of Valvular Disease in Acute Rheumatism.—Dr. Hale White and Mr. Tripp: A Case in which the attempt was made to Remove a Dermoid Tumour which growing in the Spinal Canal pressed upon the Spinal Cord.—Dr. F. E. Batten and Dr. Prickett: A Case of Acute Encephalitis in a Child following Influenza.

British Laryngological, Rhinological, and Otological Association (11, Chandos-st., Cavendish-square, W.)—4.30 p.m. Discussion on Conditions of the Throat and Larynx Simulating and Predisposing to Tuberculosis (opened by Mr. Lennox Browne).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (5th).—Royal College of Surgeons of England.—4 p.m. Prof. A. W. M Robson: The Surgery of the Stomach.

London Throat Hospital (204, Gt. Portland street, W.).—4.30 p.m. Mr. Waggett: Accessory Sinus Suppuration (Post Graduate Course.)

Medical Graduates' College and Polyclinic (22, Chenies street, W.C.)—4 p.m. Dr. Galloway: Consultation. (Skin.)

Royal Institution of Great Britain.—5 p.m. General Monthly Meeting.

West London Post-Graduate Course (West London Hospital, W.)—5 p.m. Dr. Ball: Methods of Treating Throat, Nose, and Ear Affections.

TUESDAY (6th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m. Sir W. H. Broadbent, Bart.: Consultation (Medical.) 6 p.m. Dr S Taylor: Class. Applied Anatomy and Physical Diagnosis. Demonstration I.

National Hospital for the Paralysed and Epileptic (Queen-square, W.C.)—3.30 p.m. Mr. Gunn: Optic Neuritis.

Royal Institution of Great Britain.—3 p.m. Prof. E. Ray Lankester: The Structure and Classification of Fishes.

WEDNESDAY (7th).—Royal College of Surgeons of England.—4 p.m. Prof. A. W. M. Robson: The Surgery of the Stomach.

St. John's Hospital for Diseases of the Skin (Leicester square, W.C.)—4.30 p.m. Dr. Eddowes: Seborrhœic Eczema and Rosacea. (Post-graduate Course.)

Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 p.m. Mr. J. Berry: Clinical Demonstration.

Hospital for Consumption and Diseases of the Chest (Brompton).—4 p.m. Dr. Habershon: Cases of Cardiac Hypertrophy.

THURSDAY (8th).—Royal College of Physicians of London.—5 p.m. Dr. F. J. Waldo: Summer Diarrhœa with special relation to Causation and Prevention. (Milroy Lecture.)

West-end Hospital for Diseases of the Nervous System (73, Welbeck street, W.).—5 p.m. Clinical Demonstration:—Mr. H. W. Dodd: Cases of Visual Disorder in relation to Diseases of the Nervous System.

The Hospital for Sick Children (Gt. Ormond-street, W.C.).—4 p.m. Mr. H. S. Collier: Demonstration of Selected Cases.

Charing Cross Hospital.—4 p.m. Dr. M. Murray: Demonstration of Medical Cases. (Post-graduate Course.)

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.)—4 p.m. Mr. J. Hutchinson: Consultation. (Surgical.)

London Skin Hospital (40, Fitzroy-square, W.).—4 p.m. Mr. J. Startin: Baldness and its Causes.

FRIDAY (9th).—Royal College of Surgeons of England.—4 p.m. Prof. A. W. M. Robson: The Surgery of the Stomach.

Royal Institution of Great Britain.—9 p.m. Prof. F. Clowes: Bacteria and Sewage.

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.)—4 p.m. Mr. R. Lake: Consultation. (Eye, Ear, Nose and Throat.)

SATURDAY (10th).—Royal Institution of Great Britain.—3 p.m. Right Hon. Lord Rayleigh: Polarised Light.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. II. of 1899, which was completed with the issue of Dec 30th, and the Title-page to the Volume were given in The Lancet of Jan. 6th.

VOLUMES AND CASES.

Volumes for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

Communications, Letters, &c., have been received from—

A.—Messrs. R. Anderson and Co., Lond.; A. B. C.; Messrs. Allen and Hanburys, Lond.; Mr. R. B. Anderson, Lond.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (*to ensure insertion the same week*) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Three Lectures

ON

THE SURGERY OF THE STOMACH.

Delivered in the Theatre of the Royal College of Surgeons of England on March 5th, 7th, and 9th, 1900,

By A MAYO ROBSON, F.R.C.S. Eng.,

MEMBER OF THE COUNCIL AND HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE; AND SENIOR SURGEON TO THE LEEDS GENERAL INFIRMARY

LECTURE I.

Delivered on March 5th.

Mr Vice-President and Gentlemen,—My first duty is to thank the Council for doing me the great honour of electing me to this important chair a second time and for permitting me to take as the theme of my lectures a subject which, though until recently considered of purely medical interest, is, as I shall hope to show, one in which surgery may lay claim to many conquests, and one which in the future is destined to become more and more surgical, from the fact of many of the diseases being only capable of relief or cure by operative treatment. My excuse for giving these lectures must rest on the experience I have had in this branch of surgery, thanks to my position on the staff of a large general hospital and to the kindness of my many medical friends, for I have operated on about 150 stomach cases and have seen a very much larger number where a question of surgical treatment arose, but in which operation was either declined or not advised. When beginning the preparation of these lectures it soon became manifest that it would be impossible to cover the whole ground of stomach surgery in the time at my disposal. I propose, therefore, to devote the greater part of the time to the so-called benign diseases and only to discuss very briefly the operative treatment of malignant disease.

Anatomical Considerations.

This is not the time to enter minutely into the anatomy of the stomach, but it may be useful to refer to a few facts bearing on its surgery.

The stomach varies more in size, position, and relations than any other organ in the body, for it may be so contracted, as in stricture of the œsophagus, as to be hidden from the surface and tucked up under cover of the ribs and the liver, it being then little more than a thick-walled canal; or so dilated, as in some cases of stenosis of the pylorus, as to occupy every region of the abdomen, even extending into the true pelvis Specimens on the table illustrate these variations. Normally only a small part of the body of the stomach and pylorus are in contact with the abdominal wall, fully two-thirds lying under cover of the ribs nearly vertically. The cardiac orifice is on the left of the ninth dorsal vertebra and the pyloric sphincter on the right of the eleventh or twelfth vertebral bodies about an inch to the right of the middle line, its position on the surface of the abdomen corresponding with the angle between the xiphoid and right costal cartilages The channel of entrance is vertical, but that of exit passes downwards, backwards, and to the right. The lesser curvature, which is directed to the right, is nearly altogether on the left of the middle line. The lower border or greater curvature lies normally well above the umbilicus and is also nearly altogether on the left of the linea alba.

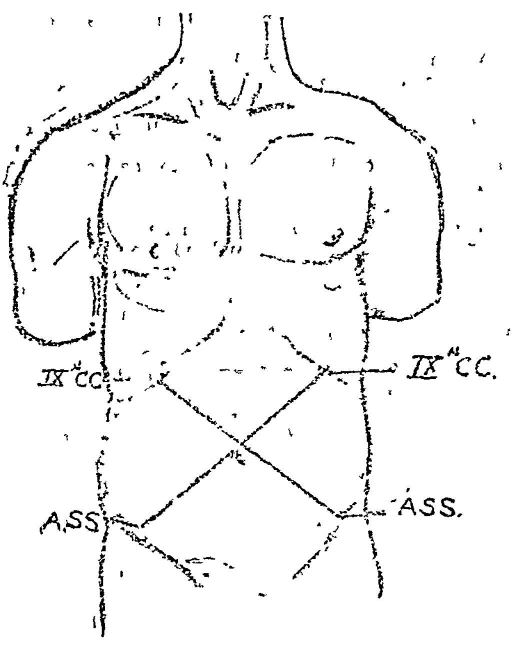
On opening the stomach to explore the cardiac orifice it must not be forgotten that the cardiac end of the stomach not only *extends some distance to the left* of the orifice of entrance, but that it reaches quite an inch above it, like a dome, and lies under cover of the left lung. The cardiac orifice is the only fixed portion of the stomach and corresponds to the seventh left costal cartilage near the sternum. The pylorus, on the other hand, is very moveable and if fixed is abnormal It may be at the middle line, or if the stomach is distended it may be two inches to the right of the middle line, and I have seen it lying behind the pubes. The pylorus is sometimes spoken of as the pyloric valve, but it is really a sphincter and the channel should easily admit the passage of a finger. Its patency may be ascertained without opening the stomach by invaginating a portion of the anterior wall of the stomach and pressing a finger into the channel at the time that the left hand is fixing the pylorus. If there be any growth or thickening this is readily felt at the same time. Another method of ascertaining the patency or otherwise of the pyloric orifice is to pick it up in the longitudinal axis between the index finger and thumb, when the digits will readily feel between them the pyloric ring and estimate its size and condition. In the normal healthy condition the lesser omentum readily allows the pylorus to be drawn into view and brought forward, but if there be disease the lesser omentum is frequently shortened and the pylorus fixed deeply under cover of the liver so that it can only with difficulty be exposed and manipulated. Under these circumstances an operation such as pyloroplasty may have to give place to gastro-enterostomy. The thickness of the walls of the stomach gives a good hold for sutures and renders it peculiarly amenable to surgical treatment, and the great vascularity of the organ completely does away with the fear of gangrene after the application of sutures, though at the same time its vascularity makes it specially prone to violent hæmorrhage from ulceration.

The lymphatics empty themselves into the glands situated in the free border of the lesser omentum and in front of the great vessels of the abdomen; they are of first-rate importance in cancer of the stomach when gastrectomy is under consideration, as are also the glands in the great omentum. They should always be examined before excising a growth of the pylorus or stomach, as in case of their being found enlarged a less severe operation will afford equal or even greater probability of relief than would a futile attempt to do a radical operation. The nerves of the stomach, derived from the pneumogastric and the sympathetic, are very abundant, and not only account for the very severe pain caused by ulceration but also for the severe collapse produced by injury; but it is a mistake to suppose that manipulation of the pylorus is always attended by the severe shock suggested by the experiments made by Mr. Crile, for in many cases I have freely handled the stomach and pylorus and operated on them without my patient experiencing more shock than would be expected after any abdominal operation. When the pylorus is adherent and the parts have to be much dragged on severe shock is not infrequently seen, but this is due to interference with the sympathetic nerves and other structures behind the pylorus.

The relation of the sympathetic nerves with the seventh, eighth, and ninth spinal roots accounts for the superficial tenderness of the epigastrium in ulceration and for the reflected left shoulder blade pain. This is well shown in pyloric adhesions complicating cholelithiasis where, though the pain is originally on the right, passing to the right infrascapular region, as soon as the pylorus becomes involved in the inflammation or tied down by adhesions, the pain passes also to the left infra scapular region.

The usual method of dividing the abdomen into nine regions is purely arbitrary and is probably continued because it has been so long in use; but the fact of there being as many as 30 different methods of subdivision shows that as yet a really satisfactory one has not been arrived at. I venture to suggest the use of two lines, from the lowest points of the right and left anterior superior spines of the ilium to the opposite costal margins at the most prominent part of the ninth costal cartilage respectively, the lines crossing near the umbilicus, thus dividing the surface of the abdomen into a right and left and an upper and a lower region, the immediate neighbourhood of the umbilicus, within a circle of two inches diameter, being known as the umbilical region Possibly this method of mapping out the abdomen has been suggested previously; if so, I am unaware of it It is the one to which I shall refer in my subsequent remarks. The umbilical region contains (1) the termination and division of the aorta and part of the vena cava, (2) coils of the small intestine, (3) the stomach when dilated, (4) the transverse colon when full, (5) the remains of the umbilical vein, (6) the remains of the urachus and of the omphalo-mesenteric duct (both at times patent), (7) the termination of the duodenum, and (8) the great omentum The superior abdominal region contains (1) the liver, (2) the stomach (including the pylorus), (3) the gall bladder and bile ducts, (4) the spleen, (5) the duodenum, (6) the transverse colon, (7) the aorta and vena cava, (8) the solar plexus and semilunar ganglia, (9) the cœliac axis, (10) the pancreas, (11) the lesser omentum (with the free border containing the vena portæ, hepatic artery, and common bile-duct), and behind it the foramen of Winslow, and (12) the upper part of the great omentum. The inferior region contains (1) a part of the small intestine (chiefly ileum), (2) the bladder and the lower ends of the ureters, (3) the prostate, (4) the rectum, (5) a part of the sigmoid flexure of the colon, (6) the uterus and its appendages, (7) the iliac vessels, (8) the lymphatic glands, (9) the hypogastric sympathetic plexus, (10) the lower part of the great omentum, (11) the inguinal canals (with the spermatic cord in the male and the round ligaments in the female), (12) the cæcum and the vermiform appendix, (13) the lower part of the psoas muscles and their sheaths, and (14) the lower part of the iliac fossæ. The right abdominal region contains (1) the upper part of the cæcum and the ascending and hepatic flexure of the colon, (2) a part of the small intestine, (3) the right border of the great omentum, (4) a little of the right lobe of the liver, (5) the right kidney and adrenals and the commencement of the right ureter, (6) a part of the psoas muscle and sheath, and (7) the upper part of the right iliac fossa. The left abdominal region contains: (1) the lower and outer part of the spleen, (2) a part of the stomach if dilated, (3) the left kidney and ad-renal and the commencement of the ureter, (4) the descending colon and the splenic and sigmoid flexures, (5) a part of the small intestine, (6) the left border of the great omentum, (7) a part of the left psoas muscle and sheath, and (8) the upper part of the left iliac fossa.

FIG. 1.



The abdomen divided into four regions, upper, lower, left, and right. The transverse lines run through the ninth costal cartilages and through the anterior superior spines of the ilium

DIAGNOSIS.

Although diseases of the stomach naturally come under the notice of the physician at first the time has passed when the surgeon may feel content to accept and act on the diagnosis already made for him by his medical colleague, leaving with the latter the responsibility of a possible error; rather, he must himself go over the whole of the medical evidence and be prepared to supplement it by surgical methods, should such be required to elucidate the case or to render possible an accurate diagnosis.

The diagnosis of any stomach case necessitates both a general and a special inquiry, the former involving the questions of age, sex, occupation, habits, mental, moral, and physical condition, and the history both of the patient and of the disease; and the latter, which is the only part which we need now consider, including all the information that the surgeon can elicit by a physical examination.

Inspection.—Inspection will always constitute our first effort in diagnosis and it is important that the patient should be in the dorsal decubitus, lying comfortably in a warm room with the abdomen exposed to view. Dilatation of the stomach can often be ascertained by inspection, and it may in extreme cases be seen to occupy all the five regions of the abdomen, as shown in the diagram If the dilatation is atonic the swelling persists without visible peristalsis; but if it is due to contraction of the pylorus visible peristalsis from left to right can frequently be plainly seen. Tumours of the pylorus and of the body of the stomach are frequently visible through the abdominal wall, and in an early stage they can be seen to move downwards on inspiration; this more especially applies to cases of cancer, as in tumours depending on ulcer of the pylorus adhesions form early and fix the stomach under cover of the liver. Inspection will reveal the shallow, rapid costal breathing induced by pain at the commencement of peritonitis and by distension in the later stages, just as it will demonstrate the sighing respiration in internal hæmorrhage and the irregular catching breathing in diaphragmatic peritonitis or subphrenic abscess. It will also show the fixed and bulging ribs in subphrenic abscess and the swelling in the upper abdominal region when the pus tends to make its way forward.

Palpation.—Palpation immediately follows inspection, and of all methods which are adopted for diagnosis it is the one that we can least afford to omit. With the patient supine in bed or on a couch, the head slightly elevated on a cushion and the knees drawn up, the muscles of the abdomen are relaxed as much as possible. They can then easily be kept relaxed by talking to the patient so as to divert his attention. The flat warm hand placed on the abdomen at once perceives any irregularity or abnormality. If the upper abdomen is rigid it will raise the suspicion of local peritonitis, especially if there is tenderness on pressure. Should there be a tumour, its nodular character, if malignant, will easily be felt, and if it be an early stage of cancer of the pylorus it will in all probability be freely moveable. If there be malignant disease of the body of the organ it will move downwards on respiration but not freely from side to side. It will be found better, as a rule, to slide the hand over the abdomen and not to raise it from the surface, thus avoiding fresh defensive contraction of the muscles which will occur if the hand be raised and replaced on the abdomen. It may sometimes be advisable to employ gentle massage in order to elicit the presence of a tumour of the body of the stomach or of the pylorus due to muscular spasm, as in pyloric stenosis. In some cases of ulcer a distinct tumour may be present at one time, owing to the contraction of the muscular coat and absent at another, the tumour only being felt distinctly when the spasm is present. In diagnosing between atonic dilatation of the stomach and that due to obstructed pylorus the vermicular contractions felt under the palpating hand are of the first importance. Where, as occasionally happens, palpation is impossible on account of rigidity of the muscles or obesity an anæsthetic may be advisable. Bimanual examination with one hand in the loin and the other on the surface of the abdomen will frequently give increased information as to the size of the tumour. A tender and rigid epigastrium suggests ulcer of the stomach and the situation of the tenderness is frequently a good guide to the site of the ulcer; for instance, if the tenderness be under the left costal margin and the left rectus be rigid, especially if the patient be relieved by assuming the dorsal decubitus, in all probability the ulcer will be on the anterior surface; whereas if the tenderness is on the right of the middle line between the umbilicus and the right costal margin the probability is that the pylorus is the affected part. When there are symptoms of ulceration without marked epigastric tenderness and with increase of pain on dorsal decubitus, and relief is found by lying on the face, the probability is that the ulcer is on the posterior wall of the stomach Palpation will usually bring out the character of the tumour as to smoothness, irregularity, softness, or hardness. A nodular character of the tumour, especially if associated with fluid in the peritoneum, usually indicates malignant disease. Pulsation in an epigastric tumour is often felt, and if it is due to cancer it will be non-expansile and dull on percussion. Fixation of a tumour is suggestive of perigastritis, especially if associated with tenderness, but it may also be dependent on infiltration due to malignant disease While palpating the abdomen it is important to distinguish between surface tenderness which may be reflected and deep pain directly due to the disease which is being sought for A change of posture will then be useful—for instance, with the patient on the left side a pyloric tumour will frequently change its position considerably, especially is this so in the early stage of pyloric cancer *A modification of palpation is succussion*, which is of considerable use in determining the presence of a splash in a dilated stomach It may be safely asserted that if the stomach splash be obtained three hours after a meal the stomach is abnormally dilated Palpation of the stomach may be made more distinct by distending the cavity of the stomach with air In this way one can diagnose hour glass contraction as well as ordinary dilatation, and can also estimate the size of the cavity or cavities In subphrenic abscess on the right side palpation will show if the liver is depressed and this will form a link in the chain of evidence going to show that the abscess is between the diaphragm and liver and not in the liver itself

Percussion —Deviation from the normal size of the stomach can usually be ascertained by percussion, first with the patient recumbent and afterwards by mapping out the region of dulness when the patient is erect after he has drunk freely of water After distending the stomach with air, either through a tube introduced by the mouth or by giving a dose of carbonate of soda in solution followed by one of tartaric acid, percussion readily demonstrates the outlines of the stomach and shows the position of any tumours both with regard to the orifices and to the greater or lesser curvatures, and it also enables the diagnosis to be made between a pancreatic and a stomach tumour Percussion is also of use in demonstrating the presence of free fluid in the peritoneal cavity due to the rupture of a gastric ulcer, and for showing the absence of liver dulness under similar circumstances when free gas is present in the peritoneal cavity It must not be forgotten that dulness in the flanks may be dependent on distension of the colon with fluid and the similarity to free fluid in the peritoneum may be increased by change of posture increasing the dulness in the dependent area and creating resonance in the elevated area Again, resonance in the flanks may be created by distension of the colon with gas and excessive distension of the colon may lead to error in diagnosis by pushing the liver well under cover of the diaphragm thus leading to the belief that liver dulness is abolished by free gas in the peritoneal cavity I have known this to occur in a case of extra-uterine gestation which was thought to be due to the rupture of a gastric ulcer Where a tumour is manifest to inspection or rendered evident by palpation percussion is useful in eliciting the presence of a hollow viscus in front of it, as in diagnosing between a pancreatic and a gastric tumour, for in the former case light percussion will give resonance in front of the tumour, whereas in the latter light percussion will reveal dulness and *vice versa*

Auscultation —Auscultation is of much more importance in the diagnosis of chest than of abdominal conditions, but *it is sometimes useful in demonstrating* the splashing sounds in gastric dilatation and the gurgling or metallic sounds in subphrenic abscess containing gas In the diagnosing of stricture of the œsophagus, where gastrostomy is in question, the gurgling sound on fluid reaching the stomach is usually delayed several seconds in the presence of stricture Before performing gastrostomy for organic stricture it is of the first importance to be certain of the diagnosis Dr Ogston pointed out that in a healthy person food occupies four seconds in passing from the mouth to the stomach and if the ear be placed three inches below the angle of the left scapula an amphoric rushing sound is heard when fluid enters the stomach With one finger on the pomum Adami, with the ear in the situation mentioned, and with a watch in the hand it will usually be found when there is stricture of the œsophagus that 14 or 16 seconds elapse before fluid reaches the stomach This is a valuable addition to the ordinary well known means of diagnosis Spasm of the pharynx or of the œsophagus at times closely resembles organic stricture, hence before proposing gastrostomy an examination should be made with the patient anæsthetised

Pain —Though pain may be absent in some few examples it is present at some stage of the disease in the greater number of stomach ailments calling for surgical treatment and its character and course frequently afford the most valuable means at the disposal of the surgeon for interpreting and diagnosing ailments which present few physical signs The history of the onset of pain may show the local origin of a more general trouble For instance, in the diffused pain of general peritonitis due to the rupture of a gastric ulcer it is of the utmost importance to know whether it was preceded by pain after food and by epigastric tenderness, so that an exploration of the abdomen may be made over the site of disease and thus a great saving of time effected in the operation In one case of ruptured gastric ulcer that I had to operate on there were absolutely no previous symptoms pointing to stomach disorder, and thinking, from the profound collapse, the sudden onset, the presence of fluid in the abdomen, and the history of a missed period, that the case was one of ruptured extra uterine gestation my first incision was made above the pubes As a rule, however, the pain from perforated gastric ulcer, though ultimately diffused, will have been first felt in the epigastrium and the history will point to pain after food and probably to indigestion of long standing; there will also frequently be a history of reflected pain in the left scapular region, but in some cases of pyloric disease with adhesions to the gall bladder and liver I have found the reflected pain passing to the right scapular region Obscure recurrent abdominal pains may be dependent on a stricture or kink of the pylorus produced by adhesions, which though not sufficient to cause obstruction may produce considerable distress and disability The local and reflected pains afford much help in this class of cases

Instrumental aids to diagnosis —In subphrenic abscess the exploring syringe affords useful aid in diagnosing the presence of pus and enabling the surgeon to decide on the exact site of the incision for its evacuation Œsophageal bougies are employed in cases of dysphagia not only for treatment, but to ascertain the site of obstruction and its nature when the question of gastrostomy arises I prefer instruments made after the pattern of *bougies à boule* employed in urethral cases, they are not generally known but to my mind they present great advantage both in the ease and the safety with which they can be utilised and the facility with which they can be employed to dilate a stricture Messrs Rauschke of Leeds made my first set some years ago, and they have since copied them for other surgeons In case of starvation from stricture of the œsophagus the question of gastrostomy has to be considered, but it must first be shown that the disease is incapable of being overcome by other means Simple stricture is rare and may frequently be efficiently treated by dilatation Cancerous strictures, on the other hand, cannot be safely dilated and will require other treatment If there be a history of steady loss of flesh and gradually increasing dysphagia in a middle aged or elderly patient malignant stricture will be suspected, and if on passing a bougie it be arrested just before entering the stomach the diagnosis is rendered very probable, but if there be slight bleeding caused by the bougie when gently used little doubt will be left Spasm is most frequent in the pharynx, though it may occur in any part of the œsophagus It usually occurs in subjects younger than in those who are afflicted by malignant stricture, and nearly always in women It is, however, frequently associated with other nervous symptoms, it varies in intensity, and it usually yields to the passage of bougies without difficulty If, however, a bougie cannot be passed in a case where spasm is suspected an anæsthetic will at once settle the doubt as under its influence a full sized bougie usually *reaches the stomach when the stricture is due to spasm* alone Electric illumination may sometimes be useful It is accomplished by an apparatus consisting of a small electric lamp fixed to the end of a bougie which is passed into the stomach If the stomach is full of water an illuminated area is seen which corresponds exactly to the limits of the organ It is best demonstrated in the erect posture in a dark room In this way abnormal dilatation of the stomach can be detected and a tumour appears as a dark spot in the light field With regard to the x rays, I have found both the screen and skiagram of use in demonstrating the position of impacted coins and other foreign bodies The gastro endoscope has, however, not yet proved to be of any service

Vomited matters and the contents of the stomach —With regard to vomit, the first thing to consider is the quantity vomited at one time Nurses should be trained to estimate this carefully and also to preserve specimens on all occasions In dilated stomach vomiting usually occurs only once daily, sometimes only on every second or third day, and the quantity at one time is correspondingly large In ulcer of the stomach a considerable portion of the last meal may be brought up within an hour or two of its ingestion and the pain it has caused is thereby relieved. The smell should be considered. A yeasty smell is characteristic of dilated stomach; a habitually fœtid odour is characteristic of cancer of the stomach; and a feculent odour is characteristic of intestinal obstruction. Vomit is usually acid in reaction, but it may be alkaline in some cases of chronic dyspepsia or when there is much blood present. The most important abnormal constituent of vomit is blood. In large quantities its nature is obvious and the event is usually characteristic of simple ulcer, but in cirrhosis of the liver profuse hæmatemesis may occur owing to rupture of dilated veins. In smaller quantities the vomit has a characteristic dark appearance resembling coffee-grounds, and this may be due to cancer or ulcer. When the existence of blood in vomit is doubtful the most reliable guide is the hæmin test. Some of the material is filtered and the filtrate evaporated to dryness. Powder the residue and place a little on a glass slide, add a drop of glacial acetic acid, and heat gently; cover with a cover-glass, and examine under a high power for small dark-brown crystals of hæmin. A crystal of common salt is not necessary here, as there are chlorides present. In cancer of the stomach blood is frequently present in the vomit; often in small, sometimes in considerable, but rarely in large, quantity. Pus is sometimes, but rarely, vomited. In considering both pus and blood in a fluid said to be vomited it must be remembered that when large quantities of fluid are expelled from the lungs—e g., on the rupture of an empyema into the lung or in severe hæmoptysis—the sensation to the patient is often as if vomiting had occurred. The presence of food and the absence of frothiness will help to distinguish true vomit, while vomited blood is generally much darker than blood from the lungs. But the only reliable way is to inquire carefully into the facts of the occurrence. Pus in the vomit may arise from an empyema of the gall-bladder or a pancreatic abscess, or some other abscess bursting into the stomach or œsophagus.

Examination by the microscope is of secondary importance. In dilatation of the stomach the sarcina ventriculi is frequently to be seen, together with yeast-cells. In cancer red blood corpuscles can often be found. In reference to the diagnosis of malignant disease of the stomach the relative abundance or absence of free hydrochloric acid has been pointed out as of importance by Ewald. The patient takes a "test breakfast," consisting of a cup of weak tea and a little dry toast. An hour later the stomach-tube is passed and the contents of the stomach are drawn off. These are tested for free hydrochloric acid by Gunberg's test. The reagent consists of two parts of phloroglucin and one part of vanillin in 30 parts by weight of absolute alcohol. A few drops of the filtered contents of the stomach are mixed with an equal quantity of the reagent and the whole is evaporated to dryness in a porcelain dish. If free HCl be present red crystals will form; should there be much peptone present no crystals but a red paste will result. The absence or deficiency of free hydrochloric acid occurs in several morbid states, but its presence is a strong point against a diagnosis of malignant disease of the stomach. Hyperacidity is as characteristic of ulcer as diminished acidity is of cancer. Dr. Vaughan Harley[1] advocates the estimation of the motor power of the stomach in the following way. To test the motor power Leube's meal is the best. A fasting patient is given a quarter of a pound of freshly minced meat and a little bread, and from four to seven hours later the stomach contents are examined. Normally there is no residue five or six hours after this meal. In increased gastric irritability when the motor power is increased the stomach may be found empty between the third and fourth hour. In delayed motility without pyloric stenosis there is a residue after seven, eight, or even 16 hours.

Exploratory incision.—In only a very small percentage of cases is simple exploratory incision as a means of diagnosis necessary or even justifiable, and there can be no doubt that in some cases it has served as a cloak for carelessness or incompetence. A careful physical examination, and time and care in studying the history of the case will usually enable either an exact diagnosis or an approximate one to be made; and in the odd case the experienced surgeon can usually say that it is one likely only to be relieved by surgical treatment, though possibly the exact pathological condition may be a matter of some doubt. Where there is doubt, and delay will not be injurious, a second or even a third examination should be made, as it is well known that at a second visit new facts may be brought to light, the patient's memory may be stirred up, and small data really important but thought by the patient or friends to be too trivial to mention at the first visit may form the key to the situation; moreover, the mind of the surgeon may on the next visit focus his attention on different points or group his data differently, and so perhaps arrive at a truer conclusion. In case of doubt a consultation is advisable, in order that the case may be considered from a non-operative point of view. It must not be forgotten, however, that the surgeon must bear the responsibility that awaits the decision, and he should be careful, if a positive diagnosis cannot be arrived at and operation is decided upon, to be able to answer two questions in the affirmative. First, Can I perform an exploratory operation without adding serious risk to the life of the patient already threatened by the disease? Secondly, Is it possible that good will result from the exploration? At times the surgeon may be called on to explore the abdomen for a tumour of the stomach which it is just possible may be removed, but where it is impossible to say beforehand whether the glands are involved or the disease has invaded the adjoining parts to such an extent that the removal of the growth would be useless. Under such circumstances, when the tumour is exposed, the great gift (usually a matter of common-sense combined with experience) of "knowing when to stop" comes in, for although having made an exploratory incision may, and probably will with due precautions, have involved no risk to the patient, any interference with the tumour may inflict such injury on the growth that the surgeon is compelled to convert his harmless exploratory procedure into one of the most serious operations which, if not causing death on the table or shortly after, can lead to no ultimate good. This is sheer meddlesomeness, and for the credit of surgery, if from no higher motive, should be avoided. Very frequently, however, it is impossible to decide what surgical operation is required until the stomach is exposed and handled. I find that I have performed an exploratory operation on the stomach on eight occasions. All were in malignant cases and the presence of glands or secondary nodules rendered further operation inadvisable. All the patients in these cases recovered. In some case of abdominal injury, either gunshot, stab-wound, or even injury without external wound, the severe shock, the vomiting of blood, and the general condition of the patient may lead to a suspicion that the stomach has been injured and an exploratory operation may be justified, since in case of rupture of the stomach such an injury, if not repaired, would inevitably prove fatal.

The following is a case in point. A youth was admitted to the Leeds Infirmary suffering from shock with vomiting of blood following on a stab-wound over the stomach. As there was free fluid in the peritoneal cavity it was thought that bleeding was going on and that possibly the stomach contents had become extravasated. An exploration showed a wound of the superior mesenteric vein with bruising but no wound of the stomach. The vein was ligatured and the abdomen cleared of blood and the patient made a good recovery.

At times all the symptoms of perforating ulcer may be present without a previous history of ulceration and all that can be said is that a peritoneal catastrophe has occurred which threatens life. Under such circumstances an exploratory operation may be required. A case of this kind came under my care where a lady was seized with violent abdominal pain at the railway station. As she became profoundly collapsed she was removed to the station hotel and was seen by a medical man who called me in. The only obtainable history was that there had been no stomach symptoms, but that the patient had missed her last menstrual period for nearly a fortnight. As there was free fluid in the peritoneum, which was thought to be blood due to a ruptured extra-uterine gestation, and as the liver dulness was present, the abdomen was opened over the pubes, when free non-odorous gas escaped, showing that the case was a ruptured gastric ulcer. The opening was therefore closed and another made over the stomach, when a perforated ulcer was found and closed and the abdomen was cleansed, the patient making a good recovery.

Incision for exposure of stomach.—Although incision in the middle line between the xiphoid and umbilicus gives the readiest access to the stomach in the greater number of cases, especially if there is doubt as to what may be required, it is not always the best site, for three reasons 1 It is apt to be followed by yielding of the scar and hernia unless long rest is enjoined after the operation 2 The round ligament of the liver with its irregular adipose envelope is apt to be in the way and to prove confusing 3 To prolong the incision for further investigation is inconvenient because of the umbilicus, These difficulties, of which the first only is of importance, are obviated by an incision through the inner margin of the rectus just to the right or left of the middle line An incision on either side gives ample room, but if the pylorus is to be attacked, it is preferable on the right, if gastro enterostomy has to be done it is better on the left Afterwards the abdominal wall is sutured layer by layer and there is no fear of hernia or a weak scar being left; moreover, there need be no fear of extending the incision if more room be required The oblique incision along the costal margins is undesirable because it divides muscle so freely and exact repair by suture is difficult, especially in the case of the rectus, which so freely retracts, hence permanent weakening of the abdominal wall and ventral hernia are more likely to follow As a matter of fact, with due care in applying sutures any one of these methods may be employed and the operator should select that which will give him the best access to the parts to be manipulated Personally I prefer the vertical incision through the inner edge of the rectus where practicable

---

[1] Practitioner, October, 1899.

Gastrotomy —"Gastrotomy" is the term applied to the operation of opening the cavity of the stomach It is one of the oldest operations on the stomach, having been practised by Matthis of Brandenburg so long ago as 1602 for the removal of a knife that had been accidentally swallowed But as a diagnostic method with a view to further treatment gastrotomy is a modern procedure Exploratory gastrotomy has only been performed within the last few years and by its means an extensive and minute examination of the interior of the stomach may be made with thoroughness and safety, so that in any case calling for operation, where by other means a positive diagnosis cannot be arrived at, the surgeon is justified in opening and exploring the stomach It will be convenient that I should now consider the operation of gastrotomy as a whole, bearing in mind that one of its purposes may be simply exploratory It may be performed (1) for the removal of foreign bodies from the stomach, (2) for the removal of foreign bodies from the lower end of the œsophagus, (3) for dilating a stricture of the œsophagus, (4) for dilating a stricture of the pylorus, (5) for the removal of a polypus or other tumour projecting into the stomach, (6) for exploration in case of intractable or bleeding ulcer; or (7) for curetting a cancer of the pylorus as in Bernays' operation

The preliminary incision of the parietes has been described and for gastrotomy it requires to be rather free Flat sponges or gauze pads should then be packed around the stomach so as to avoid soiling the peritoneal cavity The edges of the wound having been retracted the stomach can now be palpated, and if anterior palpation affords no guide a tear may be made in the gastro colic omentum which will admit the fingers to palpate the posterior surface The stomach may now be drawn forward, surrounded by a sheet of sterilised gauze, and opened by a free incision in its longitudinal axis Divided vessels must be seized and ligatured and the liquid contents of the stomach must be mopped or syphoned out or pushed into the duodenum On retracting the edges of the gastric incision the interior of the stomach will be brought into view and may be further explored by the electric cystoscope if thought necessary, as, for instance, in hæmatemesis from a small bleeding ulcer If the posterior wall be the affected part it may be invaginated by the fingers inserted through the omental slit pushing it forward into the wound A tumour may now be removed an ulcer excised, a bleeding point ligatured or cauterised, the pylorus explored and divulsed, the œsophageal opening exposed and dilated, or other treatment may be carried out For foreign bodies in the stomach there is, of course, no need to make the omental wound, and an anterior incision may at once be made and the object seized and removed The incision in the stomach can be rapidly closed by a continuous catgut suture for the mucous margins and a continuous silk suture for the serous edges, a few Lembert's silk sutures sometimes being applied over all for greater security, the exposed parts may then be gently sponged over, the pads or sponges removed, and the abdominal wound closed without drainage Beyond teaspoonfuls of water for the first 24 to 48 hours all feeding is best done by enemata, and after 48 hours the amount of liquid food may be increased Later, pultaceous food may be given, but it is better not to give solid food for a week, after which the treatment is as in any other abdominal case Dr Keen[2] insists on the necessity in this as in all similar operations on the stomach, of washing out the organ before it is opened, of bringing it out of the abdominal cavity, and of protecting the peritoneum by a wall of iodoform gauze Lavage is, however, undesirable in gastrotomy for hæmorrhage

The removal by gastrotomy of foreign bodies lodged in the stomach has been attended with considerable success A preliminary distension of the stomach with fluid or air is neither advantageous nor desirable The indications for operation are the presence of a foreign body which can neither be safely dissolved nor passed, and which is actually producing or is likely to produce serious symptoms I have described in THE LANCET[3] a case in which "42 cast-iron garden nails one and five eighths of an inch long, 93 brass and tin tacks from half an inch to one inch long, 12 large nails (some brass headed) three collar studs, one safety pin, and one sewing needle were removed by gastrotomy, the patient a girl, 12 years of age making a complete recovery and being now in good health (The articles named are on the table) The value of transfusion of saline fluid in shock was well demonstrated in this case Although the operation was not very prolonged and practically no blood was lost the patient was much exhausted from excessive vomiting before operation and was pulseless after its termination, yet transfusion restored the pulse and rendered recovery possible Dr A C Bernays described a case in which, through an incision of five inches in the linea alba, he successfully removed a table knife from the stomach of a man who had swallowed it within an hour previously The patient was fed by the rectum only for four days and afterwards by the mouth Professor Loreta mentions the case of a woman who, having swallowed needles with suicidal intent suffered severe pain Gastrotomy having been performed, some needles were removed from the stomach and others were drawn out of the left lobe of the liver The patient recovered without a bad symptom and was entirely freed from her suffering Among other foreign bodies removed by gastrotomy are masses of hair forming a dense ball The most remarkable specimen of this kind is on the table, it was successfully removed by Mr Paul Swain It weighs 5 lb 3 oz Schoff[4] has collected 16 cases of hair ball in the human stomach, of which eight were removed by operation, all successfully The following statistics show the mortality in gastrotomy for foreign bodies to be 15 per cent in a series of 79 cases (in which there were 12 deaths), but the later cases show a smaller rate, and with the improved technique of to day it will doubtless diminish considerably, Crede[5] and Fricker[6] have collected 54 cases with 10 deaths, Heydenreich[7] has collected 13 cases with two deaths; Schoff[8] has collected eight cases, with no deaths, and Mayo Robson,[9] A C Bernays Halliwell[10], and Loreta have each recorded one case, with no death

The following specimens from the Hunterian Museum, now on the table show the effect on the stomach of various foreign bodies accidentally or intentionally swallowed No 2377 shows the remains of a knife swallowed two months before death No 2378 shows the blades and iron portions of three or more clasp knives swallowed by a man and voided per anum, the man recovered, No. 2379 shows the stomach from a married woman, aged 41 years, who had suffered from hæmatemesis at 17 years of age and several times later, ultimately three weeks' incessant vomiting led to death A post mortem examination showed the pylorus behind the pubes the duodenum being distended by a mass of pins weighing nearly a pound and causing obstruction There were no peritoneal adhesions The bent pins removed from the last specimen are shown in No 2380 No 2381A shows a roll of black human hair 12 inches long and weighing 5 lb. 3 oz. removed from a girl, 20 years of age, by Mr. Paul Swain[11]; the patient recovered.

Gastrotomy may be performed for the removal of foreign bodies impacted in the lower end of the œsophagus when all attempts to recover them by the mouth have failed. At the American International Medical Congress Dr. Maurice H. Richardson[12] read a paper on the Possibility of Operation on the Œsophagus through the Stomach. He had verified his statements by experiments on 60 bodies and had in one case operated successfully on a man, 37 years of age, who had 11 months previously swallowed a denture of four teeth which had become impacted at the lower end of the œsophagus. The patient had lost 50 pounds in weight and it was found to be quite impossible to extricate the plate by means of forceps introduced through the mouth. After the stomach had been opened the hand was inserted; on reaching the cardiac opening the finger discovered the plate about two inches above the diaphragm. By means of digital manipulation it was detached and withdrawn. The stomach was then carefully sutured and the abdomen closed. The patient rapidly gained weight and was soon able to resume his work. The conclusions Dr. Richardson arrived at from experiments were: that the oblique incision below the rib margin is the best; that the stomach, after being withdrawn from the abdomen a little, so as to avoid soiling the peritoneum, should be opened to the right of the convexity of the lesser curve; that the assistant should by traction on the stomach put the lesser curve on the stretch; and that the sulcus so formed is always a certain guide to the cardiac orifice. When a foreign body is impacted in the cardiac orifice it is about six inches below the opening made in œsophagotomy; and if it be firmly impacted and requires much force to detach it the safer plan will probably be to perform gastrotomy and draw it downwards a little way than to perform œsophagotomy and draw it forcibly a distance of six inches past very important structures. Dr. Ball of New York[13] recorded an operation in which he successfully detached an impacted peach-stone from the lower end of the œsophagus in a thin boy, aged 16 years, and then by attaching a piece of string to a sponge and dragging the sponge upwards from the gastrotomy opening to the mouth he was able to bring the stone with it.

Gastrotomy as a preliminary to forcible dilatation of the pyloric or cardiac orifice of the stomach was suggested by Richter and put in practice by Loreta in September, 1882. In stenosis of the pylorus divulsion has given way to pyloroplasty for the double reason of pylorodiosis having a greater death-rate and of its being liable to be followed by relapse, though it may yet be advisable in those cases of stenosis due to spasm and hypertrophy of the pyloric sphincter and in those milder forms where the sphincter may be dilated without gastrotomy by invaginating the stomach wall and gradually pushing the finger through the pyloric opening. The subject will be more fully considered under simple dilatation of the stomach.

In simple cicatricial stricture of the œsophagus near the cardiac orifice, if dilatation by bougies is impossible or has failed to keep open the stricture, the operation of gastrotomy may be performed and an attempt made to dilate the orifice from below. The operation has proved very successful. Gissler[14] has collected 10 cases and Kendal Franks 21 cases, all the patients recovering. The operation may be performed in one or two stages; in the latter case a large gastrotomy opening must be made and the dilatation proceeded with later. The one-stage operation is to be preferred, as the finger can then palpate the cardiac orifice and a mechanical dilator may be used if necessary. For subsequent operation the gastric fistula may be left if it be thought that there may be a difficulty in keeping the passage patent by bougies introduced through the mouth. The dilator that Loreta employed was after the pattern of Dupuytren's lithotomy dilator, only longer and incapable of dilating beyond five centimetres. Kendal Franks used an Otis's urethrotome from which the knife had been removed. Weiss's rectal dilator may be conveniently employed. Abbé has recently devised a method of dividing a simple stricture of the lower end of the œsophagus or of the cardiac orifice of the stomach by passing a string through the stricture from below until it emerges at the mouth, then by putting the string on the stretch and running it rapidly upwards and downwards the stricture is soon divided. The stomach and the abdominal openings are then closed and the stricture is kept permeable by the regular passage of bougies. The diagnosis is of the first importance, as in malignant disease the operation will be useless. In simple stricture of the cardiac orifice there will probably be a history of corrosive fluid having been swallowed some time previously and the symptoms will also be of longer duration than if the stricture be malignant.

Gastrotomy for the removal of a polypus or other growth projecting into the cavity of the stomach or occluding the pylorus is an operation seldom required, since simple tumours of the stomach are uncommon. The following is a good example. A middle-aged man with a long history of dyspepsia and loss of flesh came under my care for dilated stomach, which was producing the usual symptoms. The pylorus appeared to be thickened and on opening the stomach the lumen of the pylorus was seen to be occupied by a polypoid projection with a wide base, so that the passage of the stomach contents onward was almost completely prevented. The removal of the growth by scissors and the suture of the longitudinal wound transversely led to such relief that the patient gained weight at the rate of half a pound a day, and in three months he weighed between two and three stones more than before operation. The growth proved to be an adenoma. The specimen is on the table. Chaput[15] reported a case in which he excised a pedunculated adenoma from the posterior wall of the stomach, and O. B. Lyman[16] reported a case of removal of a pedunculated carcinoma of the stomach through a gastrotomy opening. Mr. Bennett[17] reports an interesting case of the kind where the removal of a simple papilloma that occluded the pylorus from time to time and led to intermittent dilatation cured the patient, a man, 35 years of age, who had been ill for four years.

Gastrotomy for exploration in the case of intractable gastric ulcer not yielding to ordinary treatment will be considered more conveniently when we discuss ulcer of the stomach.

Gastrotomy for partially removing cancerous growths in the stomach by the curette is an operation that has been performed by Dr. Bernays of St. Louis. He has recorded[18] some cases in which he had given relief by this method, but in view of the better results from gastrectomy or gastro-enterostomy it is scarcely likely that this operation will continue to hold a place in surgery, both from its uncertainty and from the danger of hæmorrhage and perforation; moreover, the relief given by the operation can only be of a very temporary nature.

GASTRIC ULCER.

Although in its earlier phases gastric ulcer comes under the care of the physician, many of the complications to which it gives rise demand surgical intervention and, in fact, can only be treated satisfactorily by surgical means. According to Brinton and Welch ulcer of the stomach occurs in 5 per cent. of all necropsies. According to Lebert, as quoted by Dr. Dreschfeld, death occurs in 10 per cent. of all gastric ulcers, 6½ per cent. occurring from perforation and 3 per cent. from hæmorrhage. Habershon says that perforation occurs in 18 per cent. of all cases of ulcer of the stomach and Brinton in 15 per cent., to which must be added the mortality of fatal hæmorrhage, which, according to Müller, occurs in 11 per cent. of all cases of ulcer, the average of all authorities being 5 per cent.; so that allowing 15 per cent. to represent the mortality from perforation and 5 per cent. that from hæmorrhage, the mortality of gastric ulcer treated medically is at least 20 per cent. But Tricomi[19] gives even a larger mortality as an argument in support of his views to treat all obstinate cases of gastric ulcer surgically; and Brinton gives the mortality from all causes in gastric ulcer as 50 per cent. It is quite unnecessary that I should enter into the numerous theories which have been advanced as to the causes of gastric ulcer or give a detailed account of its pathology, I shall therefore confine my remarks to such points as I consider have a surgical bearing.

For the present, passing over malignant, tuberculous, and syphilitic ulcers, the special form of ulcer which produces the complication calling for surgical treatment is the simple ulcer of Cruveilhier, which may be classified according to its stage and size, and to this may be added the simple erosion of the mucous membrane described by Dieulafoy which at times leads to serious or even fatal hæmorrhage. There appear, however, to be clinically two distinct forms of ulceration of the stomach—the acute and chronic; but although they seem to be separate and characteristic there are so many intermediate stages that it is a question whether or not the ulcers are as distinct as the extreme varieties would seem to indicate.

The acute ulcer is usually small and round and has the appearance of being punched out of the stomach wall; the chronic ulcer may be very large and has shelving or irregular margins. The chronic ulcer occurs chiefly in men. Dr. Seymour Taylor gives the proportion as 72 per cent. in males and 28 per cent. in females It is a disease of middle or advanced age rather than of youth, though I have operated for perforation from chronic ulcer in patients as young as 21 years. It is usually situated near to or at the pylorus, but may spread and form a tumour of the stomach extending along the lesser curvature, and it may occur in other parts of the stomach than the pylorus. It is irregular in outline and surrounded by well-marked thickening of the outer coats of the stomach. It frequently leads to adhesions, hence it is less liable to be followed by perforation into the peritoneal cavity, though it may eat its way into neighbouring organs It is frequently followed by pyloric contraction. If bleeding occurs it is usually less in quantity than in the case of the acute ulcer, but the bleeding may be severe or even fatal. The characteristic symptoms of ulcer of the stomach, pain and vomiting, may be absent until some complication supervenes, though usually they are sufficiently distinct. The pain frequently occurs from one to two or more hours after food. There is usually tenderness over the pylorus or between the xiphoid and the right costal margin. Vomiting is very irregular, but when present is characteristic. The vomit is often large in quantity, containing much mucus, and it is sometimes grumous or coffee-ground; it is often fœtid, and if there be dilatation there will be signs of fermentation with sarcinæ on microscopic examination. The symptoms vary very much and may disappear for weeks together. I have observed and operated on cases where the symptoms had been going on for five years, seven years, 15 years, and 17 years with more or less long intervals when the symptoms were in abeyance. Dilatation of the stomach is a frequent complication and is dependent on pyloric contraction the result of cicatrisation. Loss of flesh is well marked, especially in the later stages, and may be extreme, extending to half the body weight Tumour of the pylorus is frequently present and may resemble malignant disease

The chronic ulcer is usually single and very irregular and in its deeper parts it often appears funnel-shaped. The simple, acute, or perforating ulcer occurs chiefly in women and often in young single women It seems to be associated in many cases with amenorrhœa and chlorosis. The site varies, but it is frequently found near the cardiac end and near the lesser curvature, though it may attack either curvature or either surface The shape is constant, it being clean punched out and round, with little or no inflammatory exudation around it. It is frequently followed by severe and sometimes fatal hæmorrhage. Pain at the epigastrium, passing to the left infra-scapular region, comes on directly after food and is associated with local tenderness at the mid-line or on the left of the superior abdominal region. Vomiting is irregular, usually after food, and often without blood. If there be bleeding it is usually free, seldom simply grumous. Perforation is common and the ulcers may be multiple.

Complications.—Although the following complications are common to both forms of ulcer certain of them are much more common in one than the other. For instance, the acute round ulcer is more frequently followed by violent hæmorrhage and by perforation than the chronic ulcer, yet the chronic ulcer is also liable to be followed by both. On the other hand, the chronic ulcer is more frequently followed by cicatricial contraction of the pylorus with subsequent dilatation of the stomach and by perigastritis leading to disabling adhesions, also by hour-glass contraction, fistula, and tumour of the pylorus or of the stomach, serious atonic motor deficiency, severe gastralgia with uncontrollable vomiting, cancer of the pylorus, tetany, chronic pancreatitis, abscess of the liver, chronic hepatitis, profound anæmia (resembling the pernicious form), stricture of the bile-ducts, jaundice, catarrh of the gall-bladder, and other complications depending on invasion of the neighbouring organs. Both forms are accompanied by pain, by great loss of flesh and strength, and at times by subphrenic abscess. It will be at once perceived that surgery is intimately concerned with and is in fact the only effectual treatment in many of these complications, some of which I propose to treat in detail.

Diagnosis.—The well-known symptoms of pain after food with vomiting and bleeding as shown by hæmatemesis and melæna are usually sufficiently characteristic of gastric ulcer, and in the present lectures it is not necessary that I should enter very minutely into the question; but no surgeon can afford to pass over the diagnosis, which he must confirm personally before deciding on the question of surgical treatment. Doubtless before he sees the case it will have been settled that the patient is not suffering from simple gastralgia due to anæmia and hyperæsthesia of the stomach, owing to the absence of localised tenderness and of hyperacidity of the gastric juice as well as from the irregularity of the vomiting and pain which may occur independently of meals, but he may be called on to negative cancer of the stomach which will usually be indicated by the presence of a tumour, the absence or diminution in quantity of free hydrochloric acid in the vomit, the presence of coffee-ground vomiting and of cachexia, and the occurrence of the disease usually at or after middle life. The diagnosis between gall-stones and ulcer will usually be indicated by the irregularity of the paroxysms of pain, which in gall-stone colic occur quite independent of food, by the character and site of the pain, the presence of jaundice and the character of the vomiting, which in cholelithiasis usually comes on soon after the pain begins and persists long after all food has been rejected. To diagnose between ulcer of the duodenum and ulcer of the stomach, the occurrence of the former more frequently in men and after middle age, the presence of melæna with or without hæmatemesis, the pain occurring from an hour to two hours after food and the tenderness on the right of the abdomen will usually be sufficiently characteristic.

I would here point out as bearing on the site of the ulcer the importance of the character and site of the pain, which in an ulcer of the stomach is usually definitely localised and associated with tenderness on pressure The tender area is in the upper abdominal region, the position being more or less to the right or left of the middle line, according to the site of the ulcer. For instance, an ulcer on the anterior surface of the stomach near the cardiac end is usually associated with tenderness between the left costal arch and the mid-line, and relieved by the dorsal decubitus, but if the pylorus be involved the tender spot is between the right costal arch and the mid-line and the pain is relieved by lying on the left side and increased by turning to the right. An ulcer on the posterior wall of the stomach gives rise to less epigastric tenderness and the pain is felt more in the back beneath the left scapula or close to the spine opposite the attachment of the tenth and eleventh ribs, If adhesions have formed between the pylorus and liver or gall-bladder, the pain may radiate towards the right infra-scapular region. When the ulcer is on the posterior wall the dorsal decubitus increases the pain which may be relieved by lying on the face or leaning forward, or even by assuming the erect posture. In all cases of ulcer the pain is usually increased by food, but the time of the onset of pain after eating is significant For instance, an ulcer close to the cardiac end of the stomach causes pain immediately after food has been taken or the pain may even start as the food is being swallowed; whereas in ulcer of the pylorus the pain frequently does not occur until from half an hour to an hour and a half after meals. If the pain is very severe vomiting frequently occurs, sometimes immediately after food, at others not for an hour or two, and the act of vomiting usually gives immediate relief.

With regard to hæmatemesis, which is said to occur in about 80 per cent. of cases of gastric ulcer, and melæna, which is usually associated with ulcer, but sometimes occurs without hæmatemesis, they will be considered later, for hæmorrhage is one of the important complications on which the mind of the profession, so far as treatment is concerned, is not yet by any means crystallised.

Latent ulcers are not uncommon. Savariaud gives their proportion as 20 per cent. of all cases of gastric ulcer. It is said that such ulcers are always of the acute round variety, but my experience, in two cases where I have had to operate for perforation without any previous symptoms pointing to ceration, would lead me to form a different opinion, for I ound in both considerable thickening around the ulcers, howing that the disease must have existed in a latent form or some considerable time. It is difficult to explain why ome of these ulcers should exist without producing symptoms until either perforation or violent hæmorrhage occurs. In the cases I have seen the ulcer has been near the lesser curvature of the stomach and this might possibly afford an explanation, as in this situation they would be brought less intimately in contact with food.

The following specimens from the Hunterian Museum illustrate various forms of ulcer of the stomach:—No. 2395 is a characteristic example of simple chronic ulcer of Cruveilhier or the perforating ulcer of Rokitansky from a girl, aged 17 years; it is situated two inches from the cardiac orifice in front. No 2395A is an acute ulcer from a woman, aged 20 years, which caused death from perforation in 40 hours. The perforation is very small on the anterior wall close to the middle of the lesser curvature and there is another ulcer nearer the cardiac orifice. No. 2396 is a perforating ulcer causing death in a lady, aged 22 years. No. 2400 shows some multiple round ulcers. No. 2392 is an ulcer near the pylorus in a child of five years of age who died 40 hours after an extensive burn. No. 2393 is a specimen from a woman who died from cancer of the breast; the stomach shows numerous small round and oval ulcers (hæmorrhagic erosions). No. 2398 is a pyloric ulcer showing a small perforation, and another less deep causing contraction of the pylorus. It is from a male subject. No. 2399 is a chronic ulcer of the posterior wall eating into the pancreas. No. 2402A is a chronic ulcer showing puckering and contractive result of healing. No. 2402B is a chronic ulcer showing a large ulcer three and a half inches by one and a quarter inches on the posterior wall adherent to the pancreas and the liver. No. 2414 is a pyloric stenosis from ulcer, with doubtful secondary growth. No. 2415 is a pyloric stenosis with hypertrophy of the stomach. No. 2391 shows a very small universally ulcerated stomach five inches long and six inches in the greatest circumference, with the coats from three to four lines thick, taken from an old gentleman, aged 70 years, who was accustomed to take up to two drachms of wine of colchicum for gout. For nine months before death although he abstained from colchicum he had incessant pain and vomiting.

TREATMENT OF GASTRIC ULCERS.

The treatment of simple ulcer of the stomach is at first essentially medical and when properly carried out is usually satisfactory. Unfortunately, however, in many cases treatment is stopped as soon as relief to pain is obtained and long before the ulcer is healed. I have nothing to say concerning the details of medical treatment since it is out of my province, but I would urge most emphatically that the absolute treatment advocated in the medical text-books should be carried out more systematically and for a much greater length of time, and that it should not be left off as soon as the ulcer has got to the painless, otherwise the healing, stage. Doubtless this too brief treatment is most frequently due to the impatience of the patient, but I feel sure that in hospital practice it is often due to pressure on the beds and to a desire to make the most out of them, and in private practice it is frequently due to thoughtlessness and perhaps sometimes to ignorance of how long it takes to secure healing of a gastric ulcer.

The surgical treatment of intractable ulcer of the stomach is still *sub judice*. The first operation for the cure of ulcer of the stomach was performed in 1881 by Rydygier, who resected successfully a large ulcer from the posterior wall of the stomach. In 1882 Czerny repeated successfully a similar operation and in the same year Van Keef also succeeded in a like case. After other cases of excision Doyen, in 1893, introduced the operation of gastro-enterostomy for the treatment of gastric ulcer, and at the German Congress of Surgeons in 1895 he reported 21 cases in which he attributed the relief or cure of ulcer of the stomach by gastro enterostomy to the rest induced by the operation. Czerny, Monod, Durivier, Kuster, Novard, Tricomi, myself, and many others have followed on the same lines. Besides excision and gastro-enterostomy, pyloroplasty, pylorodiosis, and pylorectomy have all been employed in the radical treatment of gastric ulcer, but the latter operation only where pyloric contraction with tumour had developed. In England, perhaps, some of us are not yet prepared to subscribe fully to the views of Tricomi,[20] who

[20] Riforma Medica, February, 1899.

draws a parallel between the treatment of hernia and that of ordinary gastric ulcer, and proposes that as hernia is treated radically with success so should gastric ulcer in properly selected cases. By radical treatment he means gastro-enterostomy, which he believes to be the best operation for gastric ulcer. He argues that the mortality in gastric ulcer medically treated varies according to statistics from 50 per cent. to 8 per cent., and says that he has collected 50 cases where the surgical treatment of gastric ulcer had been employed, not simply for the complication of perforation, but as a radical treatment for uncomplicated, though intractable, ulceration. Out of the 50 cases there were seven deaths, giving a mortality of 14 per cent., which is rather more than the mortality that Lebert says occurs in all ulcers treated medically, but Lebert under-estimates the mortality in gastric ulcer, which according to many authorities varies from 20 per cent. to 30 per cent. of all cases medically treated. If, therefore, surgical treatment can show a smaller all-round death-rate in cases of gastric ulcer that have not yielded to properly carried out medical treatment the views expressed by Tricomi, Heydenreich, and others are well worth considering seriously. Heydenreich[21] puts the matter tersely: "The death-rate for all cases of gastric ulcer is 25 per cent. to 30 per cent., but for gastro enterostomy only 16 2 per cent., and therefore the operation has less danger than the disease. Another advantage of not waiting for complications is that the patient is in better health. At any rate, cases which do not improve with medical treatment in a reasonable time should be treated surgically."

It will thus be seen that the question will have to be finally settled by a careful study of statistics, and to this end I have, with the assistance of Mr. Willmott Evans, collected 188 cases of gastric ulcer treated surgically. Of this number 157 recovered and 31 died, thus giving a mortality of 16·4 per cent. My own experience and a careful study of the subject would lead me to say that the time has not yet come for a sweeping change to be made in the treatment of uncomplicated gastric ulcer except in the way of more rigid and more prolonged medical treatment, but that when the ulcers prove intractable, or when complications supervene, medical treatment should give place to surgical treatment at a much earlier stage than has hitherto been the custom. It is unfair to the surgeon to hand over to him moribund patients, as is at present so often done, and it is in my mind unjust to the patients to persist in dosing them with medicine or otherwise treating palliatively cases that can only be benefited or cured by surgical means.

My own contribution to the subject is as follows. I find that I have operated on 34 cases of intractable gastric ulcer with various complications which in every case must have caused permanent disability or would have ended fatally, but excluding perforation, hæmorrhage, and cancer, all of which I am considering separately. Of these, 18 operations were done in private with one death, giving a mortality of 5 5 per cent., and 16 in hospital with five deaths, giving a mortality of 31 2 per cent., or if both private and hospital cases be taken together the mortality is 17·6 per cent. The difference between the private and hospital cases can be readily explained in that a large proportion of the latter were almost moribund before surgical help was sought, and though many of the cases in private were also very far advanced the treatment of such serious cases in a private surgical home, with the undivided care of special nurses and constant medical supervision, together with the comforts and advantages that such homes afford, must lead to better results all round.

The conclusions that I would urge concerning the surgical treatment of gastric ulcer are the following: 1. In all cases of gastric ulcer, except in case of perforation, medical treatment should be first tried. 2. Where ulceration persists or the symptoms recur and prove intractable to medical treatment gastro-enterostomy should be performed so as not only to give rest to the stomach but to relieve the hyperacidity of the gastric juice. 3. As a rule, direct treatment of the ulcers by excision is unnecessary. 4. Complications, such as adhesions, pyloric contraction, dilatation, and hour-glass contraction, leading to loss of flesh and impairment of health, should be treated surgically. 5 In chronic hæmorrhage surgical treatment is advisable, as it is in some cases of recurrent acute hæmorrhage, but, as a rule, acute hæmorrhages should be treated medically. 6. In perforation surgical treatment is demanded.

As it would be tedious and take up too much time to relate the particulars of my 34 cases I have selected a few examples of which the following are abbreviated notes.

Hæmorrhage, which occurs in about 80 per cent. of all cases of ulcer of the stomach, may be arterial, venous, or capillary, and curiously capillary hæmorrhage may be so free as to render it impossible to say that some large vessel has not given way, yet after death no gross lesion may be found even on careful examination. This capillary hæmorrhage occurs under two special circumstances—vicarious hæmatemesis at the menstrual period and hæmatemesis after surgical operation. The former is well known and usually yields to medical treatment, surgical treatment having signally failed on the few occasions on which it has been tried. Hæmatemesis after surgical operations is neither well recognised as an entity nor well understood, yet is often serious and at times fatal without any apparent cause and with very little to be discovered in the stomach after death. I have seen it to follow on operation for intestinal obstruction, tuberculous peritonitis, cholecystotomy, choledochotomy, hernia, ovariotomy, and simple exploratory laparotomy, and in two cases a fatal termination occurred without peritonitis or other cause than the profound hæmatemesis to account for death. That the anæsthetic was not responsible for the hæmatemesis was shown by one of my cases having been operated on under cocaine. The case was a cholecystotomy for cancer of the common bile-duct and the operation only occupied 15 minutes, yet violent hæmatemesis set in the day after operation and proved fatal in three days, and at the necropsy nothing was found in the stomach to account for the bleeding, nor any peritonitis or other condition than the hæmorrhage, to account for death. Herr Eiselberg, at the Surgical Society in Berlin, said that he had observed hæmatemesis following operation in the Konigsberg Klinik after Bassini's operation, after ligature of the omentum, after operation for omental hernia, after laparotomy for ileus and for torsion of the omentum, and after proctectomy for cancer. In some cases numerous hæmorrhages into the mucosa of the stomach and in others numerous small recent ulcers had been found post mortem. There could be no doubt as to the causal relation between the operation and the hæmorrhage. Vomiting after narcosis could not have been the cause, as in two cases there was no vomiting after the anæsthetic. In six cases, however, there was ligature of the omentum and in the seventh the omentum was probably contused. In an experiment on an animal multiple hæmorrhages into the stomach followed twisting of the omentum. At the meeting in December, 1899, of the Free Society of Surgeons in Berlin Herr Reichard related three cases of parenchymatous gastric hæmorrhage. In one cholecystenterostomy had been performed for obstructive jaundice and was followed on the sixth day by hæmatemesis; the patient died in two days, no visible cause to account for the bleeding being found in the stomach or intestines after death. In two other cases after operations in young women violent hæmatemesis occurred as if from gastric ulcer; both were operated on but gastrotomy failed to reveal any source of bleeding. Both died and the necropsies revealed no manifest vascular lesions or even ulcers. This form of hæmatemesis coming on after operation is not necessarily fatal though it is serious and demands active treatment. Free purgatives by means of calomel, and rectal feeding, with the avoidance of anything by the mouth, are the means I have employed, and usually with success. I have never ventured to operate in these cases as the indications are not clear and the patients have, as a rule, not been in a condition to bear a second operation. Capillary hæmorrhage and hæmatemesis may come on in other conditions, associated with congestion of the portal circulation, enlargement of the spleen, and general engorgements of the venous system, but these do not concern us in regarding hæmatemesis from a surgical point of

TABLE II.—EXAMPLES OF INTRACTABLE ULCER OF THE STOMACH TREATED SURGICALLY BY MR. MAYO ROBSON.

Date.	Sex.	Age.	Nature of ulcer and operation.	Description.	Result.	After history.	With whom seen.
June 25th, 1891.	M.	54	Ulcer of pylorus; pylorectomy.	Six months' history of epigastric pain with vomiting, the vomit at times being "coffee-ground." There was great loss of flesh. The tumour was felt over the pylorus. Vermicular contraction of the stomach was perceptible through the abdominal wall. Operation: Some adhesions around the pylorus were broken down, and as the tumour of the pylorus was thought to be malignant it was removed by pylorectomy, the opening in the duodenum being sutured to the lower part of the stomach.	R.	Uninterrupted recovery. On the fifth day the patient took three pints of milk and on the tenth day some chicken and other solids. He rapidly gained flesh and went home within the month. The tumour proved to be thickening around an ulcer of the pylorus, and on microscopic examination there was no evidence of growth. The pyloric orifice was almost obliterated. The after-history in this case is interesting in that contraction occurred at the artificial opening, necessitating some months later another operation.	In infirmary.
May 28th, 1895.	M.	36	Ulcer of pylorus with polypus; pyloroplasty.	Ten years' history of pain after food, indigestion, and vomiting. Of late the vomit had been large in quantity and occurring every second day. When in health the man weighed 10 st. 5 lb., but on coming under my care he weighed only 5 st. 7½ lb. and was in a condition of profound exhaustion. No tumour could be felt. The stomach was enormously dilated. Operation: On opening the abdomen the pylorus was found to be constricted so that it would not admit a No. 8 catheter. On laying open the pylorus longitudinally two polypi were found on the proximal side and these acted like a valve and closed the small passage remaining. After removing them the longitudinal incision was stitched up transversely over a bone bobbin.	R.	The polypi were reported to be malignant, but I think the after-history scarcely bore out the pathologist's report, for the man rapidly put on weight and by June 24th he weighed 7 st. 4 lb., and by July 8th 8 st. 3½ lb., and within three months he had obtained his ordinary weight of 10 st.	"
July 23rd, 1898.	F.	44	Pyloric ulcer, excision of ulcer and pyloroplasty.	Well until two years ago, when the patient had colic and loss of flesh. Under treatment apparently she recovered and regained some of the lost weight. On Sept. 15th, 1897, there was recurrence of attacks similar to that of a year before, but with pain on the right side over the pylorus. There was loss of weight and strength. The patient had for some time been an invalid and had been continuously under medical treatment for months. The patient weighed 6 st. 11 lb. There was visible peristalsis towards the pylorus which was fixed to the gall bladder, but no pain or tenderness. The liver was two inches below the costal margin, but was not nodular and there was no jaundice. Operation: The ulcer at the pylorus was adherent to the liver which formed the base of the ulcer and there was stenosis of the pylorus. Pyloroplasty was performed after excision of ulcer, the opening being sutured transversely over a bone bobbin.	R.	By Dec. 23rd, 1898, the patient had gained 1 st. 8 lb. in weight and had no trouble in digesting anything. On Dec. 23rd, 1899, Dr. T. B. Hearder reported patient as "very well" and of normal weight.	Dr. Johnstone (Ilkley).
March 18th, 1897.	F.	46	Stricture with active ulceration at pylorus, pyloroplasty.	Gastralgia for several years, relieved by food. In November, 1894, the patient vomited some dark fluid, and since then had had frequent vomiting, the longest interval being two or three weeks. There was pain in the stomach accompanied by a hard lump and often followed by vomiting. There was great loss of weight and strength. Operation: Contraction and thickening of the pylorus, the passage only admitting a No. 12 catheter.	R.	Well in 1899. There had been considerable gain in weight.	Dr. Drake (Headingley).
Jan. 13th, 1897.	M.	52	Ulcer of pylorus with stricture, pyloroplasty.	Bad health for 20 years with dyspepsia. The man had had enteric fever nine years before. For the last two years he had been much worse with pain, sickness, and vomiting from two to three hours after meals, relieved by vomiting of large amount, but never blood. There was loss of flesh, the patient's weight being 9 st. 3 lb., with emaciation and dilatation of stomach. There was no tumour. Stricture of pylorus.	R.	On Sept. 19th, 1898, Dr. Wilks wrote, "For some time little improvement; stomach now works well. Looks better than I have ever seen him." The man was well in February, 1900.	Dr. Wilks (Grassington).
Sept. 25th, 1898.	F.	41	Ulcer of stomach; gastrolysis.	Dilatation of stomach after gastric ulcer and adhesions around pylorus. The patient complained of pain at the epigastrium and on the left side. 14 years ago he first noticed the pain, which had been worse since January and was increasing in severity. The pain was paroxysmal, not worse or specially present after food, though occasionally food caused pain. Since January the patient had vomited frequently. It was years since any blood was brought up. There was no certainty of loss of weight. On two or three occasions the fæces had been blood-stained. The patient was never jaundiced. There was no fulness of the epigastrium. There was visible peristalsis with general tenderness of the abdomen on palpation, but especially over the epigastric region. Splashing sounds were obtained. Operation. Extensive adhesions were found between the gall-bladder, liver, and pylorus. A cicatrix was found in the wall of the stomach. There was no stricture of the pylorus, but it was found kinked owing to the dilated stomach dragging on the adhesions. Omentum was placed between the surfaces to prevent further adhesions.	R.	Recovery satisfactory and the patient was able to take food well. Later reports were satisfactory in every respect.	In infirmary.

TABLE II.—EXAMPLES OF INTRACTABLE ULCER OF THE STOMACH TREATED SURGICALLY BY MR. MAYO ROBSON (*continued*).

Date.	Sex.	Age.	Nature of ulcer and operation.	Description.	Result.	After history.	With whom seen.
May 20th, 1899.	F.	41	Pyloric ulcer, perigastritis, and adhesions; gastrolysis.	For months there had been pain beneath the left clavicle and indigestion with loss of flesh. The patient had recently noticed a tumour in the upper abdomen. There were dilated stomach and a moveable painless tumour in the upper abdomen attached to the liver. Operation: Perigastritis with adhesions to the gall-bladder and liver. Tumour was an abnormal projection from the left lobe of liver. The adhesions were separated.	R.	Very good recovery. In 1900 health was regained.	Dr. McGregor Young (Leeds).
May 18th, 1899.	F.	45	Perforating ulcer leading to hour-glass contraction; gastroplasty.	Nine years ago the patient had severe pain in the right hypochondriac region; she also vomited a good deal, particularly after food. The pain was not relieved by vomiting. She could take milk and soda sometimes without vomiting. There was slight swelling in the epigastric region. This attack lasted for three weeks, then the patient lost all pain, the vomiting stopped, and she gained strength. Three years ago another attack commenced with exactly the same symptoms except that the pain was on the left side instead of the right and was more severe. The vomiting was the same as in the first attacks. There was swelling in the epigastric region for a month while it lasted. Last September another attack, exactly of the same kind as the last, commenced, the pain being again on the left side. Since then she had never been free from pain for two days together. Vomiting was very soon brought on after food, and there had been a slight swelling in the epigastrium. During the last three weeks she had been rather better. The abdomen was very tender, especially in the upper part. There was a particularly tender spot just to the left of the middle line and about two inches from the umbilicus. There was no swelling of the epigastrium. Nothing could be felt on deep palpation. Operation: An incision was made above the umbilicus in the linea alba. The stomach was exposed and found to be adherent by a firm adhesion to the anterior abdominal wall just where the tender spot was. This was of about the size of a threepenny-bit. It was cut through and there was found to be a gastric fistula. On examination the stomach was found to be cicatrised at this point as the result of old ulceration so that the finger could not be made to pass the constriction. A longitudinal incision was made about three inches long through all the coats of the stomach and this was stitched up transversely over a bobbin. There was also found considerable puckering in the lesser curvature as the result of another distinct ulcer.	R.	The patient made an uninterrupted recovery. She had no pain or vomiting after the operation and steadily gained weight. Her weight on June 19th was 6 st. 4½ lb., on the 23rd 6 st. 5 lb., on the 26th 6 st. 7 lb., and on July 29th 7 st. 2 lb.	In infirmary.
Oct. 4th, 1898.	F.	32	Pyloric ulcer with contraction; gastro-enterostomy.	Pyloroplasty had been performed during active ulceration of pylorus in December, 1895. There was great relief for a time, but later recurrence of dilatation, vomiting, pain, and other symptoms, with very considerable loss of flesh. The patient was thin and anæmic; the pulse was feeble and rapid. There was marked dilatation, the stomach reaching well below the umbilicus. Operation: Gastro-enterostomy, a bone bobbin being employed.	R.	In October, 1899, the patient was well and active. By February, 1900, he had gained 1 st. 10 lb. in weight.	Dr. Salter (*Scarborough*).
August 4th, 1899.	M.	23	Pyloric ulcer and tumour of pylorus; gastro-enterostomy.	Loss of weight. Two years before the man weighed 12 st. 12 lb., but now only 9 st. 6 lb. There was pain two hours after food. For the last two months there had been vomiting on an average five times a week, which was twice of a coffee-ground character. There was enormous dilatation of the stomach. There were a pyloric tumour which was moveable and visible peristalsis. Operation: Large mass at pylorus evidently thickening due to active ulceration; glands large but not matted. Gastro-enterostomy (bone bobbin used).	R.	By August 27th, 1899, the patient had made a good recovery. He then weighed 9 st. 7 lb. and on Sept. 20th 10 st. 13 lb. He could then eat anything.	Dr. Kilner Clarke (Huddersfield).
May 6th, 1899.	M.	31	Extensive ulceration of stomach with large tumour; gastro-enterostomy.	Dyspepsia for 17 years, which had been more severe for the last 20 months. Lead poisoning was discovered and treated and a good recovery was made. 16 months before vomiting recurred and from the outset large quantities were ejected but never blood. There was recurrence occasionally of similar attacks which were always relieved by treatment. In December, 1897, the stomach reached the pubes and visible peristalsis was detected by Dr. Barrs. Relief followed dieting and lavage till March, 1898, since which time there was almost constant pain, which was not materially worse after food nor relieved by vomiting. There was loss of weight from 10 st. to 8 st. 6½ lb., and great feebleness. Operation: A large irregular tumour was found at the pylorus and along the lesser curvature, but the glands, though large, were discrete. Gastro-enterostomy was performed, a bone bobbin being employed.	R.	The patient was 8 st. in weight when he left the home on June 7th, 1898. On August 17th he weighed 9 st. 3 lb. A letter from him dated Feb. 12th, 1899, says: "My health continues perfect. I have not lost a day's work through illness since I recovered."	Dr. Barrs (Leeds) and Dr. Webster (Golcar).

view. Venous hæmorrhage may cause rapid death from perforation of the coronary, splenic, or other large veins. The portal vein has also been perforated by an ulcer of the duodenum. Owing to the more languid circulation and the small pressure of the blood a fatal result is much less likely than in perforation of arterial trunks, but if the hæmorrhage should persist or be repeated such a case would be likely to be benefited by surgical treatment. Serious or fatal hæmorrhage from the stomach is usually arterial. It may be from (*a*) the small branches which radiate between the glands in the mucous membrane, and this may occur before the ulcer has even perforated the mucous coat; from (*b*) the large arteries along the curvatures, the coronary being the most frequently affected; or (*c*) from the extrinsic arteries, the splenic being, according to Brinton, responsible for 55 per cent. of the deaths in fatal hæmatemesis. Ulcers of the pylorus and duodenum affect principally the pancreatico-duodenal and then the right gastro-epiploic arteries.

The following tables are taken from a valuable thesis by M. Savariaud and show at a glance the vessels chiefly affected.

TABLE III.—*Showing the Vessels affected in Bleeding Ulcer of the Stomach.*

Arteries.	No. of cases.	Veins.		Undetermined.	No visible orifice of vessel.	Not mentioned.	Total.
Splenic	17	Branch of the coronary ...	2	2	4	4	23
Coronary	6	Other veins ...	2	—	—	—	8
Arterioles	10	—		—	—	—	10
Total	33		4	2	4	4	47

The aorta has been perforated by ulcer of the stomach in cases recorded by Grüngeld and Stick, the hepatic artery by an ulcer of the duodenum (recorded by Broussais), and the heart itself in perforating ulcers of the stomach (recorded by Chiari, Brenner, and Finney). The peculiarly fatal nature of *hæmorrhages from medium-sized arteries* depends on the fact that the ulcer makes a lateral opening into the vessel which prevents natural hæmostasis by retraction and contraction; then the whole force of the heart is exerted on the clot which tends to form during the syncope that usually occurs when a large quantity of blood is poured out. The duration of the hæmorrhage or the interval between the first appearance of bleeding and death is of great importance surgically. The following table from M. Savariaud's thesis is therefore worthy of note :—

TABLE IV.—*Showing the Length of Survival after Various Hæmorrhages into the Stomach.*

Vessels.	Number.	Very rapid death.	Rapid death.	Longer survival.
Heart	4	1	1	2 (three days).
Aorta	2	—	—	1 (ten days).
Hepatic	2	—	1	1 (ten days).
Splenic	17	3	7	7 (from two to 18 days).
Coronary	6	1	3	2
Pancreatico-duodenal ...	6	1	3	2 (eight and 15 days).
Arterioles... ...	10	1	1	8 (from four to 15 days).
Little veins ...	4	1	1	2 (from seven to 11 days).
Capillaries ...	3	2	—	1 (21 days).

It is curious that the size of the perforated vessel does not seem to bear any relation to the time between the first bleeding and the prolongation of life; this is doubtless due to the irregular and variable amount of coagulation that occurs around the mouth of the opening and within the vessel. It is therefore impossible to diagnose the size of the vessel perforated either from the amount of the bleeding or the length of survival, for death has occurred very rapidly in some cases where the hæmorrhage has been from the capillaries or small vessels.

SURGICAL TREATMENT OF HÆMORRHAGE DUE TO ULCER.

This is a question which one cannot too carefully consider, and although statistics are apt to be misleading it is a subject in which statistical evidence is manifestly worth careful consideration. Let us first consider what is the mortality from hæmorrhage in ulcer of the stomach. Authors estimate this very differently. Müller gives 11 per cent., Gerhart from 3 to 5 per cent., Welch from 3 to 5 per cent., Steiner 6 36 per cent., Lebert 3 per cent., Brinton 5 per cent., Debove 5 per cent., Leube 1 per cent., and Dreshfeld 3½ per cent. The average of these numbers gives approximately 5 per cent., which seems to be a proportion agreed on by English physicians.

A reference to Table IV will show that in a quarter of the cases death comes so rapidly that there is barely time to consider the question of surgical treatment. In another quarter a fatal termination takes place in from 24 to 36 hours after the first onset of the bleeding. Surgical treatment in these cases of fulminating hæmorrhage has so far yielded few good results and they usually terminate fatally, whether treated medically or surgically, but in the remaining 50 per cent. of cases where repeated hæmorrhages occur, and where the interval between the onset of bleeding and death varies from a few days to a fortnight, the question of surgical treatment is well worth considering seriously.

Doubtless the desirability of stopping bleeding from an ulcer of the stomach by surgical means must have occurred to many minds before being put into execution. To Mikulicz, however, belongs the claim of having been the first to operate for hæmorrhage from a gastric ulcer. This was on Feb. 13th, 1887. Death in this case occurred 50 hours later. Roux of Lausanne was the first to perform a successful operation and that in a case of hæmorrhage from the coronary artery, in which he excised the ulcer and ligatured the artery at both ends. His case was reported at the French Congress of Surgery in 1893. At the German Surgical Congress in 1897 the subject was discussed fully by Leube and Mikulicz and the conclusions arrived at were that a patient suffering from violent acute hæmorrhage would stand a better chance of being cured by medical treatment, seeing that the mortality in all ulcers from hæmorrhage under medical treatment is only 5 per cent., but that where bleeding was repeated—in other words, where life is prolonged for several days and the hæmorrhage tends to recur—surgical treatment should be advocated. Keen and Hartmann also adopt the view of abstaining from operation except in cases of repeated small hæmorrhages. On the other hand, Dieulafoy urges immediate operation in every case of hæmatemesis in which the loss of blood exceeds half a pint and especially if it recurs within 24 hours. He relates a case of recovery after severe bleeding from ulcer in which he gathered up into a fold the ulcerated patch and ligatured it. Dr. Armstrong of Montreal[22] also advocates operation, not only in repeated small hæmorrhages which persist in spite of treatment, but in all large hæmorrhages after a second recurrence where the cause is probably gastric ulceration. In one case, that of a lady, aged 35 years, where repeated bleedings had occurred during the previous seven days, he performed gastrotomy and cauterised three separate bleeding points in the stomach, a satisfactory recovery resulting. In a second case reported by him Dr. Elder of Montreal operated upon a lady of 42 years of age on the third day for repeated hæmorrhage and ligatured a bleeding vessel in the floor of an ulcer at the lesser curvature. Unfortunately the patient died from acute anæmia the following day, though no fresh bleeding had occurred. I have myself operated on two cases of acute hæmatemesis. In one, a patient under the care of Dr. T. Churton, a man, aged 36 years, who gave a history of ulcer for over a year with great loss of flesh and strength, was suddenly seized with violent hæmatemesis, which was followed within 24 hours by a second seizure, when I was asked to see him. He was extremely weak and very thin and anæmic, and looked as if he would die if attacked by bleeding again. His pulse at the time of operation was 150. A gastro-enterostomy was performed by means of a Murphy button, the whole operation only occupying 15 minutes. For five days he did well, when he was seized with sudden pain and from this time never regained strength. Vomiting set in on the eighth day and he died on the tenth. No further bleeding occurred and at the necropsy a duodenal ulcer was found opening into the gastro-duodenal artery. The cause of death was peritonitis the result of a leakage on the fifth day, when the button began to separate. So far as the hæmorrhage was concerned the gastro-enterostomy had apparently been successful. In a second case sent to me by Dr. Peter MacGregor of Huddersfield there was a history of severe hæmorrhage twice repeated within a week and occurring in a man of 38 years of age debilitated by chronic ulcer of the pylorus with dilatation of the stomach. The patient was profoundly weak and anæmic but stood the operation of gastro-enterostomy very well and made a good recovery without any drawback and without repetition of the bleeding.

Of the 15 cases reported by Mikulicz in five cases the ulcer was not discovered, in two cases it was excised, in one case the pylorus was resected, and in another case the ulcer was cauterised. Petersen has reported from the Heidelberg Clinic six cases of hæmorrhage cured by operation, two cases by excision of the ulcer, and one case by gastro-enterostomy. Hartmann collected 12 cases, with eight deaths and four recoveries. Nearly all the deaths occurred from collapse. Besides the contra-indication to operation in acute hæmorrhage, advanced age, poor general condition of the patient, and excessive anæmia would seem to be contra-indications.

Tables V. and VI. show all the cases Mr. Willmott Evans and I have been able to collect from various sources.

The following specimens illustrate hæmorrhage from ulcers: No. 2401A shows the ulcer midway between the cardia and the pylorus near the lesser curvature, eroding the splenic artery on which is a small aneurysm. It was from a man 56 years of age. Death occurred on the fourth day. No. 2402 is a specimen from a case of fatal hæmorrhage from a large vein which is perforated by an ulcer in two places. No. 2393 shows the hæmorrhagic erosions in the stomach of a woman who died from cancer.

It will be seen that in acute hæmorrhages the mortality is very high. 27 died and 15 recovered in 42 cases, which gives a mortality of 64·2 per cent. On the other hand,

in the chronic hæmorrhages out of 19 cases two died, giving a mortality of 10 5 per cent

In considering the question of operative treatment for supposed hæmorrhage from the stomach it is well to bear in mind that bleeding may occur from the following causes: (1) from retarded circulation, as in cirrhosis of the liver and heart disease, (2) from aneurysm of the aorta and cœliac axis; (3) from miliary aneurysms in the stomach; (4) from erosion of a vessel by ulceration due to a biliary calculus, as in a case reported by myself,[23] and (5) from vicarious menstruation The operative measures that may be employed in the treatment of hæmatemesis from bleeding ulcer are (1) excision of ulcer, (2) pylorectomy, (3) cauterisation of the ulcer, (4) ligature of the ulcer and vessels *en masse*, (5) ligature of the bleeding vessels *in situ*, (6) scraping of the ulcer followed by suture of the ulcerated surface, (7) ligature in their continuity of the large vessels supplying the ulcer, and (8) gastro enterostomy After gastro-enterostomy as a rule all symptoms disappear at once and hyperacidity ceases owing to the unobstructed escape of the gastric contents

OPERATION FOR BLEEDING ULCER

On account of the fear of exciting fresh hæmorrhage it is undesirable to wash out the stomach before operating on a bleeding ulcer, and as the patient is usually anæmic and will therefore bear shock badly it is desirable to have him enveloped in cotton wool or otherwise kept warm on a heated table and to give a subcutaneous injection of strychnine before operation If it be unnecessary to give an infusion of saline fluid before the operation an assistant should be ready to perform that duty while the abdominal operation is being proceeded with, should it be called for After the abdomen is opened the stomach may be emptied by pressing the contents into the duodenum as suggested by M Terrier This saves much time, and rapidity is of great importance The surface of the stomach should then be carefully examined, as very frequently a puckering of the surface or a thickening of the coats will be noticed at the site of the ulcer, or a difference in colour may sometimes indicate its site Should the operator be fortunately able to find these indications much time may be saved, but if no indications of this sort be obtained the stomach must be well drawn forward and opened either by a vertical incision, which gives less hæmorrhage, or by an incision in the long axis of the stomach, which affords a much better view of the interior In order to avoid soiling the peritoneum thin flat sponges should be placed within the abdomen, and it is well to have a perforated sterilised gauze pad covering the stomach, the opening to correspond with the opening in the stomach The edges of the stomach should then be held open by forceps, one above and below and one at each end

The interior of the stomach must now be systematically examined, first the anterior and posterior surfaces, the upper and lower curvatures and lastly the pyloric and cardiac orifices, all of which can be done either by the naked eye or by the aid of an electric cystoscope or a reflected light If the posterior wall of the stomach cannot be efficiently examined a slit may be made in the omentum and two fingers, or even the whole hand, pushed through it and employed to invaginate the posterior wall If no ulcer can be found on the wall of the stomach the duodenum should be explored, not only by the finger, but by invagination If no ulcer be found anywhere and the bleeding proves to be capillary or from small undiscoverable ulcers, gastro enterostomy as advocated by Doyen should be performed, but if an ulcer be discovered and it be possible to excise it, that operation should be done, as it undoubtedly offers the likeliest method of cure After excision of the ulcer and ligature of the bleeding vessels the edges of the wound are brought together by sutures, of which one or two layers may be employed Should the excision involve the peritoneal coat it is desirable if possible to apply Lembert's sutures, and if it be on the posterior wall the operation may present some, though not insuperable, difficulty Should the ulcer be discovered in some region where excision is impracticable—for instance, near the cardiac end—the method adopted by Mikulicz, in his first operation in 1887, of applying the cautery may be employed This seems to have answered well in several cases, and where death occurred afterwards it was not from a recurrence of the bleeding Possibly in a case of this kind gastro-enterostomy might also be advisable by way of setting the stomach at rest, or the ulcer might be curetted; but in one case in which I simply scraped the ulcer and applied carbolic acid an extension of the ulcer occurred and led to perforation on the eighth day, so that I am not much in favour of trusting to curetting simply. If any superficial points of bleeding be discovered they may be caught up by forceps and ligatured, but this is more easily said than done, as the mucous membrane is very friable, and a ligature if drawn at all tightly tends to cut its way through; moreover, forceps easily tear the mucous membrane and may produce a larger bleeding area. A method of ligature may be employed if the ulcer is small. This has proved serviceable in several cases and is easy of application when the ulcer can be reached. This method is ligaturing *en masse*, it has been tested by experiments on animals by Dr. Eisendrath and has been shown to endanger perforation except when supported by external sutures. Ligature of the main arteries of the stomach was suggested theoretically by Savariaud when no bleeding ulcer could be discovered; it does not, however, commend itself as being safe and it has not yet been put in practice.

---

[23] Diseases of the Gall bladder and Bile-ducts, second edition, 1900

Should the bleeding be from an ulcer at the pylorus the operation of pyloroplasty may be performed, the ulcer being excised, the edges of the ulcer being united so that the *line of sutures shall be transverse to the axis of the pylorus.* I would not, however, advise pyloroplasty when there is active ulceration of the pylorus unless the ulcer can be completely excised, for in three cases of this kind I have had disappointments. In one case the patient made a good recovery from the operation but subsequently suffered from stenosis, for which a further operation had to be done. In a second case recovery took place and the patient regained his lost weight, but subsequently a tumour of the pylorus developed which was thought to be cancer and for which I had to perform pylorectomy, and the third case is the one ending in perforation which I mentioned in speaking of curetting ulcers. I think, therefore, that in cases of ulcer of the pylorus where a clean excision of the ulcer cannot be done it would be better to perform gastro-enterostomy or pylorectomy, whichever at the time may appear to be easier. So far as I can gather, the mortality of pyloroplasty in simple ulcer appears to be about 13 per cent., that of gastro-enterostomy about 16 per cent., and that of pylorectomy 28 per cent., but it is most difficult to get at genuine statistics since many single failures are unreported, and these figures must only be accepted as approximate. Wherever the pylorus is adherent, as in my experience it is in so many cases of ulcer, I should certainly prefer gastro-enterostomy, but if the pylorus be extensively ulcerated and free from adhesions pylorectomy can be almost as quickly performed as gastro-enterostomy, seeing that the pylorus is already in the hand. The operative treatment of parenchymatous or capillary hæmorrhage by any surgical method would seem to be of doubtful value, for according to a report by Petersen from Czerny's clinic of three cases operated upon for severe parenchymatous hæmorrhage from vicarious menstruation operation entirely failed to relieve, and of two other cases of post-operative parenchymatous hæmorrhage by Reichard both died.

After a careful study of reported cases as well as from personal experience I cannot help feeling that operative treatment in acute hæmorrhage gives such a high rate of mortality—64·2 per cent. as compared with from 5 per cent. to 10 per cent. in cases treated medically—that it is better in such cases to rely solely on medical means. But in the repeated chronic hæmorrhages that are responsible for quite half the total deaths from hæmatemesis the operation of gastro-enterostomy affords a reliable method of treatment, since it at the same time gives rest to the stomach and removes the hyperacidity of the gastric juice by an operation that can be done with rapidity and comparative safety; moreover, when the ulceration is at the pylorus, where it so frequently leads to hypertrophy and stenosis, the operation not only relieves the symptoms for which it was undertaken but proves curative to the disease.

EXETER DISPENSARY.—The annual meeting of this institution was held on Feb. 17th under the presidency of the Rev. E. Dupuis. The medical officers reported that 6256 patients had been treated during the year, as compared with 6164 in 1898. The financial statement showed that the income amounted to £1866 and the expenditure to £1722.

The Lettsomian Lectures

ON

PRACTICAL OBSERVATIONS ON CANCER OF THE BREAST.

Delivered before the Medical Society of London

BY SIR WILLIAM M. BANKS, LL.D., F.R.C.S. ENG.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY; EMERITUS PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, LIVERPOOL.

LECTURE I.[1]

Delivered on March 6th.

MR. PRESIDENT AND GENTLEMEN,—Naturally my first duty is to thank you for the honour you have done me in asking me to give the Lettsomian Lectures in the first year of the twentieth century. Let us fervently hope that long ere it has come to an end a remedy will be found for the fell scourge of which I propose to treat. I have in my consulting-room the well-known engraving of the founders of this society. I shall never look on the stiff but commanding figure of Quaker Lettsom as he stands in their midst without a feeling of pride that I have been permitted to be one of those privileged to assist in celebrating his name and fame. The roll of those who have delivered these lectures contains so many distinguished names that I may well feel some diffidence in trying to follow in their footsteps, but I take courage from the recollection that this is not the first time that the Medical Society of London has deputed me to address them.

EXPERIENCE AND STATISTICS IN MEDICINE.

When a man has to prepare an address the choice of a subject is generally a most difficult matter. If he has nothing of a very distinctly novel character to offer to his hearers it is probably best for him to give them his experiences on the subject with which he is most acquainted. If he has any judgment and discretion in him he may do something useful in this way, for in the medical profession advances are so rapid that they are apt to become bewildering. The record of a long personal experience under such circumstances may be of service as a kind of steadying medium. Moreover, these lectures, although nominally delivered to you, do really reach the majority of the medical public, and one of their prime uses is to present to that public at given periods a synoptical view of all that is known of the subjects which they embrace up to the moment. I will endeavour, then, to put into them my experiences of cancer of the breast during the past 33 years, in which I have been engaged in surgical practice. It is true that in the absence of statistics experience can only produce "impressions and recollections," and the professional statistician holds all "impressions and recollections" in the greatest contempt. He holds that figures can never lie; but, on the other hand, it has long been painfully manifest that nothing can be more lying and delusive than statistics if they are not properly used. In the first place, their collection must be made with the utmost accuracy and with perfect purity of heart and calmness of mind. With medical statistics the temptation to gloss over and soften down unfavourable figures is very great and requires that a man shall summon to his aid all his integrity. Again, when a man presents to you a vast mass of statistics, compiled at the expense of much time and labour, it is practically impossible to go over them with him and you have no choice but to accept them. As a result many errors have been long handed down from book to book until some disagreeable doubter has arisen who has exposed them. Finally, even when the statistics are absolutely correct, the most erroneous deductions may be drawn from them, and from the same figures two men may extract the most opposite conclusions. If anybody wants to know how statistics may be manipulated let him consult the literature of the opponents to the contagious diseases Acts of the antivivisectionist, and the antivaccinationist—all of them prepared by persons of the most superior virtue. Nobody wishes to deny to statistics their great value and their proper place, but one must also stand up for the value of those views which many successes and many failures have engrained on the mind of any man endued with an average amount of good sense and judgment. If, then, a man be not a waverer, blown every way by the wind of opinion, he ought, at the end of an experience extending over the life of a generation, to have come to certain firm and definite conclusions about many things; and if he proposes making these views public he must express them in a firm and definite fashion. This necessarily exposes him to the charge of egotism and dogmatism. The former I shall endeavour to avoid as far as in me lies, but, should I occasionally become dogmatic, I pray you to put it down to the exigencies of the situation, compelling me, as they do, to give my own particular views about cancer of the breast while freely according to every other surgeon the liberty to advocate his views and declare mine entirely wrong.

---

[1] Lectures II. and III. will be delivered on March 19th and April 2nd, 1900, respectively.

The Increase of Cancerous Disease and its Cause.

Before coming to cancer as it specially manifests itself in the female breast I should like to say something on certain points on the general question of malignant disease which legitimately forms part of our present subject. Most medical men are of opinion that the number of persons who die from cancer in proportion to the number of the population has been steadily increasing. Very voluminous statistics from the returns of the Registrar General and from the returns of deaths in individual towns and counties seem to prove this very emphatically. My own impression, apart from any knowledge gained from statistics, is strongly to the same effect. It is true that the impression of a surgeon who sees a great deal of cancer must be received with care, for it is doubtless the fact that as a man's practice increases he may see more of certain cases than he used to do because his friends, knowing that he is interested in them, send them to him. Thus he may come to think that the same thing is happening in the practice of everybody and that there is a general increase in those diseases all round, whereas the increase is in reality only in his own sphere of observation. In order to protect myself from falling into this mistake I have summoned up my recollection of the year 1861–62, when I was a dresser in the wards of Mr. Syme in the Edinburgh Royal Infirmary. Mr. Syme had a reputation then as being indisputably the first surgeon in Scotland, so that I am sure my old fellow-students of the period I mention will bear me out when I say that the pick of the surgical cases in the south of Scotland were sent to him. I have a very vivid recollection of the run of cases I saw and I possess a note-book to-day containing many of them. Now cases of cancer, although not uncommon, were rare compared with the numbers in the practice of my colleagues at the Liverpool Royal Infirmary and myself at this moment. They were objects of curiosity and interest to us students. I can only remember once seeing a case of cancer of the rectum. So that I am able quite clearly, after an interval of 38 years, to assert that the number of cases in the wards of any one of the surgeons of the Liverpool Royal Infirmary at this day is much larger than I can remember in the wards of so distinguished a man as Mr. Syme, who drew his patients from a great area. This is more than a mere impression. This is a fact. The arguments used against the alleged increase of cancer are that it is more apparent than real on account of the improved diagnosis of modern days producing greater accuracy in death certificates, and on account of necropsies being formerly the exception in hospitals, whereas they are now the rule. In his very able article in the *Practitioner* for April, 1899, Dr. Arthur Newsholme advocates these views with much ability. On these points I will, with your permission, gentlemen, once more revert to my student experience. I think it may be fairly admitted that the character of the medical teaching at any given epoch is a barometer which gives the level of the knowledge of the mass of practitioners at that same period. In 1861 Miller, Syme, Spence, and Patrick Watson were the chief surgical teachers in Edinburgh. I assert that their knowledge of surgical cancer on the surface of the body and in the ends of the intestinal tract was as accurate as that of any surgeon of the present day. Bennett, Laycock, Begbie, Gairdner, and Sanders taught medicine, and I am unable to see any notable difference between their ideas of internal cancer and their methods of diagnosing it as compared with now. If mention be made of the brain, spinal cord, and nervous system generally, then at the time I speak of absolutely nothing was known about them and the improvements in the diagnosis of them can only be appreciated by one who has witnessed the change. But this is not the case with the diagnosis of cancer. I do not like to say much about the increase in the number of necropsies at hospitals because I cannot make a positive statement on the question beyond this, that in my student days at Edinburgh—and I imagine the same holds good of all the great London hospitals—every effort was made to secure post-mortem examinations when possible. One would too gladly wish that Dr. Newsholme were right, but immediately following his paper is one by Professor Roswell Park of Buffalo who states that in England and Wales the death-rate from cancer has risen from one out of 5646 of population in 1840 to one out of every 1306 of population in 1890—that is to say, that in 50 years the death-rate has increased between four and five times—and he makes this astonishing statement: "A careful study of all these tables permits one to make the following startling prophecy. If for the next ten years the relative death-rates are maintained we shall find that ten years from now—namely, in 1909—there will be more deaths in New York State from cancer than from consumption, small-pox, and typhoid fever combined." With every wish, then, to give a good deal to the theory of better diagnosis and more numerous necropsies I cannot bring myself to believe that they account for more than a moderate amount in the increase of cancer mortality.

Local Distribution.

Has locality anything to do with cancer? This is a matter upon which a great deal hinges, but from personal experience I cannot give any information. It is unlikely that any hospital surgeon will be able to do so, for he who has obtained any reputation for the operative treatment of cancer draws his patients from such varied sources that the question of locality as affecting them is void. On this subject information of any moment can only be obtained by collecting great masses of statistics, and even then the deductions therefrom will have to be made very cautiously and judiciously. The first attempt in this direction was made by Mr. C. H. Moore of the Middlesex Hospital in 1865, and to him is also due the merit of being the first who boldly drew the attention of the profession to the inefficient operations for cancer which were performed in his day. To his courageous protest is due the modern principle of free removal. As we all know, Mr. A. Haviland's labours have been those of a lifetime and his tables of statistics are a marvel. In 1868 he read to the Medical Society of London in this very room his first paper on the Geographical Distribution of Cancer among Females throughout England and Wales during the Decennial Period 1851-60. He found that 4·33 cases of cancer occurred in every 10,000 females and 1·94 in every 10,000 males. Leaving untouched the decennial periods 1861–70 and 1871–80 he recently investigated the period 1881–90. He then found 7·30 cases in 10,000 females and 4·30 cases in 10,000 males—i.e., 0·42 more than double among males and 1·28 less than double among females. Admitting these statistics as true, two things are clear: (1) that there has been a great general increase of cancer all round; and (2) that this increase is much more marked in males than in females. The following are Mr. Haviland's "last words":—1. That the districts having the highest death-rates from cancer among females were invariably associated with seasonally flooded areas traversed by, or in close propinquity to, seasonally flooded rivers. 2 That geologically these high mortality districts were characterised by alluvium and subsoils of clays of every variety of age and formation. 3 That the districts having the lowest death-rates from cancer were situated on elevated land where the drainage was good and the physical features of the country such as to preclude the possibility of floods, where rivers derived their sources, and where, in fact, they were not fully formed. 4. That geologically these low mortality districts were characterised by the oldest, palæozoic rocks, especially those of the carboniferous limestone period, the liassic, oolitic, and cretaceous limestones. The closing sentences of Mr. Haviland's intensely interesting paper (1899) run as follows: "Thus at the end of this brief sketch of the medical geography of cancer we find ourselves asking the same question that rose to the lips of my audience in November, 1868, 'How is it that *limestones* are always associated in England and Wales with the *lowest* mortality from cancer and *flooded clays* with the *highest?*' This question still remains unanswered and will still so remain until the subject is taken up in earnest by the medical profession; for it is a field, I find, after 30 years of working in it, that cannot be made to produce fruit without the toil of many labourers. When the above question is answered light will begin to fall on the cause of cancer." It is a most refreshing thing to find this veteran statistician placing his figures at the disposal of his fellow practitioners, modestly admitting his inability to draw sure and certain conclusions from them and encouraging other workers to supplement his labours so that some determination on a most important question may be reached.

Let us turn to Mr. W. Roger Williams's most interesting work on Diseases of the Breast, published in 1894—a work evincing an infinity of statistical learning. It is a model of how research by statistics should be employed, in which figures are fairly handled and deductions prudently made. Furthermore, it is a mine for all those to dig in who are interested in the question of cancer. Mr. Williams thinks there is much to be said in favour of the opinion that in this country cancer is specially prevalent in flat, low-lying, fenny districts—noting especially Cambridgeshire and the adjacent counties of Northamptonshire, Huntingdonshire, and Bedfordshire. He observes, however (taking his figures from the Forty-seventh Report of the Registrar-General), that all low-lying and seasonally flooded districts have not a high cancer mortality. The very large area drained by the Severn and its tributaries, for instance, has throughout a low average mortality from this disease. In fact, as we shall see presently, his view of the cause of the increased cancer mortality is very different and is not geological at all.

One would very much like to enter into the question of cancer houses, but it is, perhaps, digressing too far from my subject which really has relation to the disease as it occurs in the breast. In this country Mr. Haviland, Mr. D'Arcy Power, and Mr Law Webb of Ironbridge, as well as certain French and German surgeons, have written papers on the subject of profound interest—indeed, almost terrible interest. Still more evidence, however, will have to be forthcoming to make a clear case, for the liability to fallacious deduction in such a subject is so serious that a great mass and weight of testimony in its favour will yet have to be produced.

CAUSE OF THE INCREASED CANCER DEATH-RATE.

Up to the present time, while statistics have already cleared, and are at this moment rapidly clearing up, many points about cancer, nothing definite has as yet been furnished by them as to the reason of its increase. That being so, there is a fair and reasonable ground for the employment of the "impression" begotten of experience. For many years the more I have thought over this matter the more forcibly does the idea present itself to me that it may be due to the great increase in the amount of food consumed by the people of this country during the past half century. At all events, this view is worthy of being argued. I think it was first put into my head a long time ago by Sir James Paget. I took a lady suffering from incurable cancer to him. He gave her some directions, and one was that she was to eat as little as possible—to try to starve herself, in fact. His long experience had taught him that to starve the body as a whole probably meant starving the cancer locally. *Per contra*, if that be a correct notion, then cancer ought to be connected with well-nourished bodies. Certain it is that the disease has not appeared to me to affect the weakling, the tea-shrivelled, mummy-like old maid, or the ill-fed, more than half-starved drunkard who never has any money to spend on good food. Its most numerous victims are well-nourished persons, with plenty of beef and fat about them, and often with a fine, healthy colour in their cheeks. In summing up the many operations I have done for cancer of the tongue my recollection of the patients is for the most part of biggish, powerful men with large, strong jaws which were hard to saw through when sawing had to be done. The better the nutrition and the younger the patient the more deadly and rapidly growing is the cancer. Take what is termed a fine, "buxom" woman, 30 or 35 years of age, with cancer of the breast, and her chance of permanent cure even by the most extensive of operations is almost *nil*. It is true that cancer is uncommon in the young during the period of development of the body and of the functional activity of organs, so that in one sense it is a disease of "degeneration"; but this has nothing to do with the good nourishment and muscular development of the body in middle life. Being assured in one's own mind that well-nourished, well-developed, healthy people are the most numerous victims of cancer the questions at once arise, Is the increase of cancer in any way synchronous with an increase of nutrient material—i.e., of food—throughout the country and are people in consequence better nourished? There cannot be a doubt of it. Ever since the passing of the Corn Laws bread has been cheap and plentiful, while during the last 20 years the importation of animal food from other countries has been enormous. The increased wages and emoluments of all classes in this country have enabled them to purchase freely of the best there is to be had in the whole world of things to eat and drink. Our working classes fare admirably. Our better classes eat infinitely too much—especially of animal food partaken of at breakfast, lunch, and dinner. But for the athletic tendency of the age and the general passion for games and exercises which pervades all classes this over-stuffing must have proved very dangerous. I am pretty well convinced that when a man is over 45 years of age excess in food is perhaps worse for him than excess in drink. Apparently one of the results of too much nourishing food is the production of a widely spread second-rate kind of gout of a different type from the acute and furious attacks produced in former days by the copious drinking of beer and port wine. Moreover, I think distinctly that it has also to do with the production of the cancerous diathesis. This is also the opinion of Mr. Roger Williams, who, while admitting Mr. Haviland's topographical statistics, cannot agree with him in his geological views but inclines to think that cancer areas are also the areas where the people are best nourished.

The stock answer to what may be called the "over-nutrition" theory is that vegetarians and rice eaters are just as subject to cancer as gross feeders and flesh eaters, and this statement goes on being very steadily repeated from one book to another. I am not prepared to admit this. Cancer is not so rife in Ireland, where feeding has been poor and very largely of a vegetable character, and where improvement in the living of the people has not proceeded *pari passu* with that in England. The report of the Registrar-General for the decade 1881–90 shows that in 1881 in England one death in 36 was due to cancer and in Ireland one death in 47, while in 1890 in England there was one in 28 and in Ireland one in 40. Ireland, therefore, does not rise to the level of England. Mr. Roger Williams has a most interesting chapter of facts in this connexion. He tells that Billings of the United States showed that there were two cases among the whites to one case among the blacks. From what can be learnt of the whole continent of Africa, that vast country enjoys a remarkable immunity from the disease, especially the Egyptian area and the northern parts. At the Cape cancer is common among the whites but very rare among the natives. All through the tropics the disease is distinctly rare. In India the general opinion is that it is not common and that when it does occur neither the rice-eaters nor the meat-eaters are exempt. It is true that certain surgeons—McLeod, Hendley, and Lawrie notably—hold the opposite opinion, but I notice that their experiences are drawn almost entirely from hospital work, and refer chiefly to the number of operations occurring in large hospitals. This seems hardly a sound argument. All that it proves is that a number of cases of cancer came into large hospitals and consequently that in a huge country there must be many cases of cancer; but if statistics are to be of any avail the proportion of cases to the actual population is absolutely necessary to make any fair deduction. It is like the death-rate from snake-bite. To an Englishman who never sees such a thing the sum total of these deaths seems appalling. It is not till one takes the proportion to the astounding population of India that the insignificance of the loss of life from this cause becomes apparent. If there were no knowledge of the exact population of Lancashire, and if a person were to walk round the wards of the Liverpool Royal Infirmary and estimate the cancer mortality of the county from the number of cases found in these wards, his view of the prevalence of the disease would be a most alarming one.

At this moment the Massachusetts State Board of Health is instituting an inquiry into this question. Its circular states that, "Every year there is an increase in the reports to the State of the number of deaths from cancer, even when allowance is made for age and greater population. By some it is alleged that this is due to an increase of the disease itself; by others that better diagnosis and more careful registration will account for it. Furthermore, the infectious nature of this disease, caused by a possible parasite, and its contagiousness have been strongly urged." I believe that the great general increase of cancer is for the most part admitted and that Dr. Newsholme's idea that it is not a real but only an apparent increase due to better knowledge and more accurate registration of the disease is entirely erroneous. But, even were we to admit his views, it would not account for the fact that during the past 30 years the comparative cancer mortality of the sexes has altered in a most singular manner, so that whereas the disease was formerly more prevalent among females it has now become more prevalent among males, and is becoming increasingly so.

Now, do drunken habits account for more cancer? I am certain that confirmed drunkards are not more liable to it than other people. Besides, drunken habits are rather diminishing than increasing. Does syphilis account for it? I have never been able to trace any connexions whatever between syphilis and cancer. It is true that leucoplakial bald patches and specific surface ulcers of the tongue and mouth are places where epithelial cancers arise, but they do so, not in virtue of any special syphilitic taint, but just as they arise from irritation of any kind, as from a sharp-edged tooth. Mr. Williams, out of 165 female patients suffering from cancer of the breast, did not find a single one of immoral character. Do bad water, bad housing, and bad sanitary arrangements account for it? This is impossible, for, in nothing have we improved so much as in improved sanitation—in improved water-supply, drainage, and in housing and clothing. Will increased nervous tension from our rapid existence due to the development of steam and electricity account for it? It would seem reasonable to suppose that this cause is likely to produce all sorts of nervous troubles and arterial or cardiac degenerations, but not cancer. Is it due to the fact that there is a great saving in the early periods of life and that more people live into what may be called the cancerous age? The Registrar-General's statistics show that the number of persons of 25 years of age and upwards out of every 1,000,000 living persons was just the same in the decade 1881–90 as in the decade 1871–80. There has, therefore, been no increase in the proportion of persons who live into the cancerous age.

What great change, then, has taken place in the national life? Richer and more abundant food. You will note particularly that it is the male, who eats the heavy food in ever-increasing quantities, while the female remains much as before in her eating, and note along with this that it is men now who suffer most severely from cancer and not women as formerly. Again, in all England the most tainted places are London, the Thames Valley, and the counties adjoining the metropolis, where the most luxurious habits and the best living prevail, and it has been pointed out that, even in the capital itself, the parts where those in easy, comfortable circumstances, who are supplied with more than the necessaries of life, abide show the highest mortality. It is curious to note that amongst the very highest mortality rates for occupations are those which include commercial travellers, coachmen and grooms, merchant seamen, maltsters, brewers, innkeeepers, butchers, and plumbers Most of these certainly are persons likely to eat and drink abundantly and not take too much exercise—persons who live well and do not work off their spare products. Singularly enough, medical men figure low in the list.

In conclusion, let me quote Mr. C. H. Moore's statement, made many years ago, that "cancer is eminently a disease of persons whose previous life has been healthy and whose nutritive vigour gives them otherwise a prospect of long life."

THE PARAMOUNT IMPORTANCE OF EARLY DIAGNOSIS.

As one goes on seeing case after case with gentlemen in general practice one gets to find out that, even with the highest standard of modern education, a great many errors are still being committed by medical men in the matter of the early diagnosis of mammary cancer. Now, seeing that in the matter of its cure we have nothing but free removal to fall back upon the smaller the amount of disease the better the chance of cure. Early diagnosis is therefore of paramount importance. If this can only be steadily crammed into the minds of students and practitioners a remarkable increase in the number of permanently successful operations will ere long result. This is the real line of improvement at the present moment—not in devising extravagant operations for cases that are past praying for. It is true that in the very early stages of a mammary cancer a certain and positive diagnosis cannot be made, even by the most skilled and experienced surgeon. Nobody, therefore, expects that of the general practitioner, but I have found that when the patient comes and shows her medical adviser a small lump in the breast, if it does not seem anything very formidable he is unwilling to frighten her, talks vaguely about a "swollen gland," and generally is apt rather to make light of the matter. There is a phrase I know well which must have cost a great many people their lives, "If it doesn't bother you don't bother it." It is a most destructive axiom. Then the patient goes home, the lump grows and she sees it growing, but she buries her head in the sand and repeats to herself that her medical man did not attach any importance to it and so nothing can be going wrong. In due time she becomes terrified and repairs to her medical attendant There is a distressing scene, and they then repair together to the surgeon, who says that he thinks he can get the disease out but he is not sure. Now what I would implore my brethren in general practice to do is to cease regarding any lump in the breast, however small, as harmless or unworthy of the utmost attention. No man can tell what is going to become of a small lump in the breast. All strangulated herniæ are now operated upon without delay if they will not go back, so all lumps in the breast ought to be cut out if they will not speedily disappear. As to frightening the patient, there is no necessity for unnecessarily alarming her, but, even if it were so, how much better that she should get a needless fright in the beginning than be ultimately terrified by the dreadful intimation that her doom is sealed and that a brief period of agony is all of life that is left to her. My advice to a general practitioner would be that when a patient comes to him with the smallest lump in the breast he should at once send her to a surgeon. If she be a poor person he will assuredly have a surgical friend who will see her gratuitously for him. If I were a younger man I dare not say this, but I can now. If an absolutely certain diagnosis cannot be made on the moment the point is to get the patient to visit the doctor month by month to let him see what is happening to the lump. It seems hardly credible, but on several occasions I have seen a patient in consultation with her own medical man about an early mammary swelling. It has been impossible just then to give a certain opinion about it. Treatment has been suggested, and a strong recommendation made that the swelling should be carefully watched, and yet, after a year or more has elapsed, they have so muddled up matters between them that the patient has been brought back with a pronounced cancer. This is a statement of fact and not an ideal picture. We have just been considering various conditions relating to cancer upon which have been brought to bear, ingenious speculations, supported by statistical researches involving years and years of labour. All these researches are not of the faintest moment (considering the nature of the solitary method of treating cancer of the breast which we possess) compared with the value of early recognition of the disease. Every effort should be made by teachers to inculcate the doctrine of early recognition upon students, for if there is a hopeful day to come for the sufferers from cancer of the breast it will be when women have been taught by the medical profession to present themselves on the slightest symptom of anything being found wrong with the mammary gland. Too often at present they hug their distressing secret and only part with it when it cannot be concealed and small wonder it is when one reflects that the present generation are still under the influence of the depressing tales told them by their mothers about the horrors of cancer of the breast, and the terrible and useless operations performed for its relief. I hope that my medical brethren will forgive my speaking in this very forcible manner about what appears to be a very simple thing. It is a very simple thing, but, simple as it is, it is the real secret of the future of the operative surgery of cancer, and we are not getting what we ought out of it. Let me not be supposed to reproach my profession with ignorance (for I trust I can recognise the many mistakes I have made myself), but to expect omniscience from the general practitioner is absurd. I consider that the range and extent of his knowledge is astonishing, but the early diagnosis of many mammary enlargements will defy the most experienced touch. It is only by early coöperation between medical attendant and surgeon that the patient's chances can be saved to her.

CONSTITUTION AND HEREDITY.

One of the terrible mistakes of former days, which gave cancer the character of being even more hopeless than it is, was the idea that it was purely a constitutional disease. To remove it in one place was useless, for it would just break out in another. Now the modern scientific inquirer, whose first consideration is too often to sweep contemptuously aside all that his predecessors have excogitated, asserts that there is nothing constitutional whatever about cancer—that it is a purely local disease, and that it is certainly an infective one. It seems odd why there should be any difficulty about the question. It a long time since Laycock first described the diathetic tendencies of the body and how they influenced all the illnesses which attacked that body on its way through life and often so modified them that they were almost unrecognisable, so changed were they from their usual types. Paget used to draw our attention very vividly to the remarkable way in which the gouty diathesis affected surgical disease. We know, nevertheless, that it does not necessarily follow that because a man has a diathetic tendency, it need ever become obviously manifest. He may go through a long life and never show it until some *contretemps* brings it to the surface An old friend of mine, whose male relatives to a man were full of gout, lived to over 70 years without a trace of it. He drank champagne and port most days, but he was small and thin and a passionate sportsman, so that he staved off the gout by great physical exercise. At last one day he fell off his shooting pony and hurt his ribs, and while lying in bed recovering from the injury he had a serious attack of gout in the foot. For the next two or three years of his life it never left him and it killed him with acute cerebral trouble at the last. If in place of "gout" we were to put "cancer" into this little case there would be really no difference. But that cancer should in some way be set agoing in a particular spot of a perfectly healthy man's body by the process of infection and should then produce a constitutional state—apart from mere spreading by lymphatic channels—is with our present knowledge difficult to realise. If you were to take a fine, wholesome, clean-blooded man, the descendant of a race who had for generations been free from all morbid diathesis, and put tubercle into him you could not make it spread. It would die out locally. It requires a distempered constitution, like a sour, impoverished soil, to give the appropriate pabulum for pathological weeds, which seed and spread through it and ruin it. We know now how the tubercle weed gets sown. The cancer weed may yet be caught and bottled too. When we think what an absolute revolution has taken place in our views about tuberculous disease we must not despair about cancer. It is a curious thing, however, to remember that while the North Italian peasants regarded phthisis with the greatest dread as an infectious disease, scientific medical men were the very persons who scouted the idea. Long-continued experiences are worth something after all.

As to heredity, it behoves us to be very careful how much importance we are to give to this in a difficult case of diagnosis of a tumour of the breast where side issues have to be taken into account. By the public without doubt too much value has been always attached to it. The patient consoles herself with the belief that hers cannot be a cancerous tumour because nobody in the family was ever known to have such a thing. Unfortunately we can only put the matter in this way—that, while the want of history of a cancerous tendency inherited from her progenitors is no proof that the patient's disease is not cancer, the existence of it among several near relations is distinct evidence in the direction that it is so. There have been attempts made on certain abstruse developmental grounds to overthrow the possibility of the hereditability of acquired (diseased) variations, notably by the philosophical teaching of Weissmann, but nothing has come of them. A great deal of philosophical froth has been beaten up and much learned verbiage has been poured about, but I have never seen abstract philosophy do much in disease. Our knowledge, our most useful knowledge, has been gained empirically. Patient collectors of facts have told appalling histories of whole families who have died from cancer and have disseminated it among their descendants, which are now so numerous and well authenticated as to leave no doubt in the mind of any surgeon (not a philosopher) as to the existence of heredity, and what we have to do is to attach to it its appropriate value clinically, and by no means to consider that the absence of heredity is proof of non-malignancy in a tumour. It is true that, as a general rule, cancer in a family seems very erratic in its visitations and appears to jump over a generation, but we may take a simple view of the question thus as explaining these irregularities. What figures seem to show is that the inherited infectivity of cancer is not strong and dies out most likely at the end of a couple of generations. In the midst of a family among whom cancer was never known a healthy man develops (catches?) cancer and throws the gloomy pall of hereditary diathesis over his children and grandchildren. A son shows it but his children escape, while a niece—the originator's grandchild—shows it. The rest escape because the match has not been applied to the tinder, just like my friend who escaped hereditary gout till he met with an accident towards the end of a long life which set it ablaze in him. It is impossible to resist coming again and again to ask "What is the match?" Meantime until a very clear answer is given to this I see no occasion for throwing overboard what knowledge we already possess.

Dr. Boswell Park in his chapter on the Frequency and Nature of Cancer in the *Practitioner*, already alluded to, writes as follows :—Next with regard to the actual nature of this disease. First of all it is possible to sweep aside, with one or two possible exceptions, everything that has been brought forward until recent years as an explanation of this disease. The old theories of irritation, of perverted nerve-centres, of heredity, &c., cannot for a moment stand in view of the searching scientific methods of to-day. We have gotten as far as this at present, that we know that cells act as they do in producing the disease either as the result of some external or of some internal stimulus. The exact character of this stimulus is not yet certainly demonstrated, though things point more and more towards its parasitic—i.e., its potent living-influence." To the first part of this statement I entirely demur because I am so old-fashioned as not to have got far enough to sweep aside all that experience has accumulated until I have something to put in its place. With regard to the second part it seems to involve on the part of Dr. Park what an old Scotch judge called "a plain perception of the obvious." What we all want to know is "What is the match?" and there is no certain answer to that as yet.

As regards traumatism we are all very prone to produce some distinct reason why a disease should have come to us. That it should come spontaneously is a stigma upon the soundness of the constitution, and so we wish to find out a cause. The natural liveliness of the imagination in females makes it very difficult to apportion with anything like accuracy the exact amount of credence to be placed in their statements. I must say that I have never been able to make out that milk abscesses or the scars of incisions for them have ever been the starting points of cancer, and, curiously enough, although the patients have mentioned the existence of these things I do not remember having heard them distinctly and directly attribute their growths to them. After all, if cancer ever develops in inflammatory products it is in those of a very chronic and not in those of an acute nature. I never heard, furthermore, any statements from the patients that pressure from corsets or that irritation of the nipple by suckling had produced the complaint. On the other hand I have very often heard most clear and circumstantial histories narrated in which blows were asserted to have been the primal cause of the trouble. It has been held as an argument against the effect of traumatism that men are very much more liable to blows on the breast than women and most rarely have breast cancer. I very much doubt this. Take a number of men at 50 years of age and an equal number of matronly, full-bosomed women of the same age, and it stands to reason that the latter will get more knocks on the mammæ than the men. Moreover, they are always in the way of getting knocks from young children or from articles of furniture, such as cribs and bedposts, among which they are always working. Besides, what is a man's breast after all? A little mass of fibrous tissue with some rudimentary gland stuff in it the small size of which would save it from many blows which a big, soft, vascular female breast must encounter. Moreover, it is contended that if blows caused mammary cancer the lesions would be multiple, but this just shows how things appear differently to different people, for I do not suppose that if a woman gets an injury to her breast she gets it in the form of a series of thumps all round so as to produce multiple cancers. I have received very succinct accounts from intelligent women of blows from pieces of furniture or kicks from young children in which there was pain immediately afterwards sufficiently severe to fix the exact place in the breast in the memory. Then the pain has gone away and they have almost forgotten the circumstance until some day a lump is found at the old site of injury. Were the allegation true that the injury directs the woman's attention to a tumour which is lying concealed in her breast already, then she would discover it at once on receipt of the injury, but this is not the history of these cases. The history is that of an interval after which the lump comes painlessly. Many of the patients whose histories I have ascertained were far too intelligent to have invented the story after finding the lump. Mr. Roger Williams says that in examining the cases of 137 women, one out of four made statements as to previous traumata. I should hardly have thought so many would have done so, for, supposing we put one half of them out of count at once as imaginary it would leave one case in eight in which there was not improbably some truth in the patient's statement. After the way in which the vulgar but rooted belief in the infectiousness of phthisis of the Italian peasant has, in the light of modern discovery, triumphed over the contemptuous disbelief of the whole world of medicine, I am not disposed to abandon all belief in the statements of women whom we will even admit to be anxious to find a cause for their malady. Constant repetition from different sources strengthens even a weak tale, provided the evidence be steadily in the same direction. I have investigated these stories too often not to feel that, stripped of all exaggeration, there is a distinct element of truth in them. Remember, I do not make any attempt to assert that cancers of traumatic origin are at all frequent, but I believe in the possibility, and, indeed, in the strong probability, of their occurrence. I cannot see anything irreconcilable with our pathological knowledge in the idea of a blow leaving behind it a certain limited area of chronic inflammation in which the gland epithelium should begin to grow and then burst its bounds, just as I am certain it does in chronic mastitis. Dr. Boswell Park says: "The supposed intimate relation which injury bears to cancer is of no more importance than that upon which the clinicians, and even the pathologists, used to place so much stress in tuberculosis. There are still those who claim that the predisposing cause of most tuberculous joint diseases is previous injury of some character and there are still those who look for a similar mechanical cause of cancer in virtually every case." I am not one of those who look for a mechanical cause of cancer in virtually every case, but I venture to say that there is no practising surgeon in this country who has much to do with joint disease who does not recognise the immense importance of wrenches, blows, and sprains in the production of the early inflammatory changes in and about joints which ultimately end in what is known as articular tuberculous disease. I was educated in exactly the opposite view—viz., that the tales which mothers told about injuries to their childrens's joints were all nonsense, and I was forced out of this belief by the irresistible arguments of experience.

One feels the more inclined to this view from the knowledge that acute traumatic malignancy is a well-recognised disease. Scattered throughout the medical journals are so many cases of its occurrence that no possible doubt can be entertained about its existence. In the *British Medical Journal* for 1882 are two short but very interesting papers on the subject by Mr. Barwell and Mr. Harrison Cripps, also a third by my friend Mr. Puzey of Liverpool detailing in a most interesting manner the history of a man who was struck over the sternum and in whom there was developed at the spot a sarcoma. It is true that, in all the cases which I have read about, sarcomata and not carcinomata supervened, and therefore the disease is rightly named "acute." But if injury will, so to speak, on the spot start into existence the swift-growing tumour of the connective tissue, why should it not at a longer interval give rise to the slow-growing tumour of glandular lining epithelium?

THE SANITARY CONDITION OF IRISH NATIONAL SCHOOLS.[1]

By ANTONY ROCHE, M.R C.P. Irel.,

PROFESSOR OF MEDICAL JURISPRUDENCE AND PUBLIC HEALTH, CATHOLIC UNIVERSITY MEDICAL SCHOOL; EXAMINER, ROYAL UNIVERSITY; FELLOW OF THE SANITARY INSTITUTE.

THAT the health of the individual and the community depends largely on their surroundings being sanitary is now universally admitted. That this rule is specially applicable to the young is acknowledged by all sanitarians, and that therefore their schools, wherein they spend so many hours, should meet all the requirements of modern sanitation will hardly be contested by anyone devoting any consideration to the subject. The growing and undeveloped structures of children, their close contact in schools for a number of hours, their less power of resistance to cold and other depressing influences, all render them remarkably susceptible to the causes and spread of disease. An inquiry, therefore, into the sanitary conditions of our national schools is not alone interesting but of great practical importance. According to the last official report there are no less than 8651 of these schools in Ireland and on their rolls 808,467 students. I have for some years been making personal observations and inquiries into the sanitation of these schools; as, however, my sphere of observation has not extended over many parts of Ireland I will rely rather on the evidence of the inspectors of these schools and on official returns. These inspectors have had ample and extended opportunities of observation, they cannot be expected to be prejudiced against the system of which they form a part, and therefore when they speak so plainly of the insanitary condition of many of these schools their opinion may be trusted as impartial. I will now read some extracts from the reports taken from the last available report of the Commissioners of National Education.

Mr. A. Purser, head inspector, North Dublin Group of Districts, reports, Jan. 25th, 1898: "In my last report I referred to the necessity of requiring that schoolhouses should be suitable, kept in proper repair, and adequately warmed in cold and wet weather, and I again express as my opinion that 'the Commissioners should not tolerate the existence of national schools without offices unless under very exceptional circumstances, and should refuse salary for winter months if adequate fires for heating the schoolroom are not provided. It is not an extravagant supposition that a large part of the sickness among the children of the country is brought on by badly ventilated schoolhouses, combined with want of due warmth in wet and cold weather.' It is downright cruelty to have a schoolroom for the poorly clad children so cold that an inspector, even with a heavy overcoat on, feels chilled in hands and feet. But the providing of offices is not enough; they must be kept in a sanitary, clean, and decent state; and any serious neglect of this matter should be visited with heavy punishment where the fault does not lie with defective construction of these buildings. 'No credit is given, by the present system of paying teachers, for cleanliness, neatness, or ornamentation for house and premises; none for regard to the health and comfort of the pupils; none for the educative example of decency and order, so these are naturally neglected in a greater or less degree.' A considerable number of recently built vested schools that I have visited are very unsatisfactory structures, faulty in plan, unsound in construction, and, as a result, rapidly falling into bad repair. Within the last month I visited a pair of schools in the county Wexford, which had not been occupied a single week, built at the public expense by a grant of two-thirds of the nominal cost. It is probably no uncharitable supposition that these 'two-thirds' given by the Commissioners covered the whole cost of the building. The roof was not staunch; fittings, such as the boot-scrapers at the doors, had already given way; the woodwork was rough and unplaned and hence the varnishing will be of little avail in keeping it clean; it was also so fresh that the joints were everywhere opening; at the corners of the rooms where the ventilation tubes are placed one could see daylight through the wall and the

---

[1] A paper read before the Statistical and Social Inquiry Society of Ireland on Feb. 20th, 1900

If such suggestions were adopted I have no doubt that the health of our children would be greatly improved and that the schools would be object-lessons in sanitation and cleanliness, which in many cases they certainly are not at the present time.

Dublin.

A CASE OF RUPTURE OF THE BRACHIAL PLEXUS.

BY PURVES STEWART, M.A., M.D.EDIN., M.R.C.P.LOND.,
ASSISTANT PHYSICIAN TO THE WESTMINSTER HOSPITAL,
AND
MAYO COLLIER, M.S.LOND., F.R.C.S.ENG.,
SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

CASES of rupture of the brachial plexus are somewhat uncommon and the following instance is of value, not only because of the remarkable extent of injury to the plexus, but also because it exemplifies several interesting physiological points.

A man, aged 33 years, was admitted into the North-West London Hospital in the early morning of Sept. 6th, 1899, in a state of semi-consciousness. He had been found by the police lying on the road, apparently having fallen from a machine road-brush that was in the vicinity. No one witnessed the fall and it was only elicited some days afterwards that he had been in charge of the machine. On admission the patient was only partially conscious; he was noisy, struggling, and difficult to manage, but he did not show any evidence of having been drinking. There was a wound of the left side of the head in the parietal region which apparently involved the scalp only. No fracture of the skull could be made out. The house surgeon did not detect any paralysis of the face or limbs at the time, though it is certain that the right upper extremity must have been paralysed. The right pupil was, however, observed to be smaller than the left. There was a contusion extending from the side of the neck on the right side over the right shoulder to the front of the axilla. There was no other evidence of injury. The semi-consciousness and restlessness soon passed into a quiet coma. He was watched for signs of increasing compression of the brain, but the coma gradually passed off and at the end of a week the patient was quite conscious. He then stated that he had not had anything to drink for many hours before the accident. He remembered pulling up at a coffee-stall and then starting off again, but after that he remembered nothing. The patient's wife stated that he was subject to epileptic fits at long intervals. His right arm and hand remained severely paralysed, no improvement whatever ensuing.

On examination on Nov. 13th, 1899 (ten weeks after the injury), the patient was found to be a healthy-looking man of fair intelligence. His right upper extremity was obviously totally paralysed. He had a bald patch over the right parietal eminence, the result of an old injury which he had received eight years before, possibly during an epileptic fit. The optic discs and all the cranial nerves appeared to be normal and there was no motor or sensory abnormality of the face, trunk, or limbs, with the exception of that in the right upper extremity. All external ocular movements could be executed to their full extent. There were, however, slight horizontal nystagmoid jerks on turning the eyes to the left or upwards, but none on looking to the right or downwards. The reflexes in the lower limbs, both superficial and deep, were normal. No abnormality could be detected at the root of the neck on either side. There were no swelling and no tenderness on palpation, but passive abduction of the right shoulder was painful.

With regard to the cervical sympathetic the pupils were unequal, the right (three millimetres) being slightly smaller than the left (four millimetres) (see Fig. 1). They contracted normally to light and during convergence. Both pupils dilated when shaded but the dilatation was distinctly better marked, both in degree and in briskness, on the left side than on the right. On pinching the neck the cilio-spinal reflex was absent on the right side but normal on the left. The right eye was a little sunken and the right palpebral fissure was distinctly narrower than the left (see Figs. 1 and 2). On dropping a few minims of solution of cocaine, however, into the right pupil it dilated well and the palpebral aperture widened.

Examination with regard to the sensory functions revealed that there was absolute anæsthesia to touch, pain, and temperature over most of the right upper extremity, the anæsthesia including the entire hand and forearm and extending far up the upper arm. Two strips of normally sensitive skin survived, however, one on the front of the upper arm (see Fig. 2) over the upper part of the biceps muscle, the other on the inner and back part of the upper arm over the triceps. A narrow "tongue" of anæsthesia ran upwards along the axillary side of the arm, separating those two areas (see Figs. 3 and 4). There was complete loss of sense of position on passive movement at the right elbow, the wrist, and the fingers. The sense of position was normal at the right shoulder and at all the other joints of the body. When the patient moved his right arm passively by means of his left hand he felt as if he had a "phantom right hand" hanging constantly by his side with its palm facing backwards.

As to the motor functions, the movements of the scapula were apparently normal although the right trapezius seemed a little weaker than that on the left side. The patient could brace back both scapulæ equally well, bringing the whole vertebral border of each scapula towards the middle line—i.e., the rhomboid muscles were normal. The inferior angle of the right scapula at rest was a little more prominent than that on the left side (Fig. 3), but there was no "winging" of the scapula on pushing forwards against resistance when the arm was held horizontally forwards (i.e., the serratus magnus was not paralysed). The right shoulder was distinctly flattened from wasting of the deltoid, the pectoral muscle was wasted, and the supra spinous fossa was hollowed out (see Figs. 2 and 3). Immediately below the right acromion process there was a gap into which the finger could be put, which was due to downward displacement of the humerus. This gap disappeared temporarily when the elbow was passively supported, but it reappeared at once on withdrawing the support. The distance from the acromion process to the external condyle of the humerus when the limb hung unsupported was two inches more on the injured side than in the sound limb (see Figs. 2 and 3). There was absolute flaccid paralysis of the right shoulder, elbow, wrist, and fingers. The muscles were soft and flabby, and the limb dangled loose in a flail-like manner. The latissimus dorsi was paralysed on the affected side and, unlike its fellow, could not be felt to contract when the patient coughed. Th supinator and triceps jerks were absent in the paralysed arm whilst on the left side they were both brisk.

The state of the electrical reactions, &c., was as follow There was no reaction to the strongest faradaic shocks in t right pectoral, the deltoid, the biceps, the triceps, or a muscle of the upper arm, the forearm, or the hand. The rig trapezius reacted normally. The right deltoid, the bice and the extensor muscles of the fingers being selected testing with the galvanic current, they showed mar diminution of excitability with sluggish contraction, being > KOO. The skin of the right hand was red congested and was much colder than that on the sound There were no cracks, ulcers, or other trophic changes i skin or nails.

There are several points of considerable interest i case. With regard to diagnosis, the fact of the patient admitted in an unconscious state with a bruise on the lef side of his head and with paralysis of his right arm suggested to some observers that the paralysis was due to a cerebral injury. The profound anæsthesia of the limb, however, was against such a theory; moreover, the paralysis was of a flaccid type, unlike the rigidity of a cerebral paralysis. Subsequent examination showed the presence of marked muscular atrophy and of the reactions of degeneration. Such a combination of anæsthesia, motor paralysis, and muscular atrophy pointed at once to an extensive lesion of the peripheral nerves supplying the upper limb.

Eight weeks after his accident the patient had another epileptic fit in which all the limbs were convulsed, with the exception of the paralysed arm This is of interest when i is contrasted with what would have been the case had th paralysis been due to an injury in the region of the moto centre for the right arm, in which case the convulsion wou probably have affected the paralysed arm and might ev have commenced there. The probability, therefore, is th

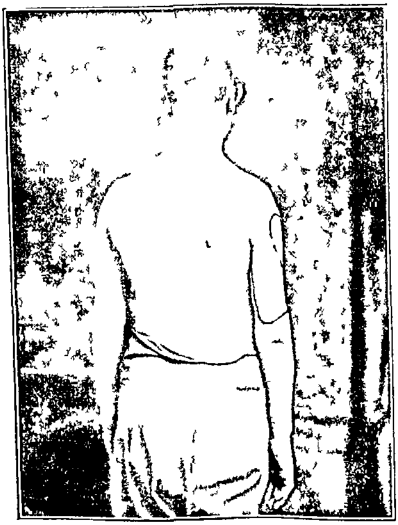

Fig. 4.

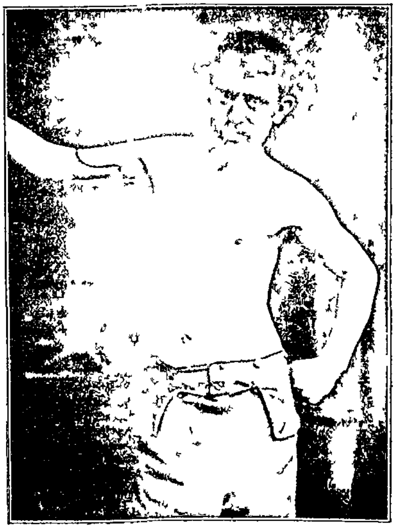
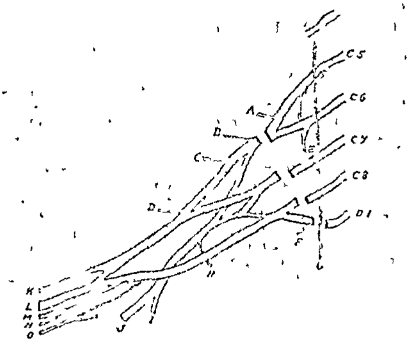


TO ILLUSTRATE A CASE OF RUPTURE OF THE BRACHIAL PLEXUS BY DR PURVES STEWART AND MR MAYO COLLIER

the patient sustained his injury by falling during an epileptic fit under his own cart, the wheel of which ran over his right shoulder and the lower part of his neck.

The accompanying diagram of the brachial plexus will serve to recall the chief anatomical distribution of the plexus. It will be observed that in this case the nerve to the rhomboids and that to the serratus magnus escaped, whilst all the other muscles supplied by the brachial plexus were totally paralysed. This proves that the lesion must have been one which affected the upper trunk (formed by the fifth and sixth anterior primary divisions) below the point where the nerve to the rhomboids is given off, but above the point of origin of the suprascapular nerve. The nerve of Bell, supplying the serratus magnus, arises by branches from the fifth and sixth roots respectively, which are given off before the fifth and sixth roots join to form the upper trunk of the plexus, so that a lesion of the upper trunk would leave the serratus unaffected, as was here the case. The seventh and eighth cervical and the first dorsal roots were all completely paralysed, and we can say definitely that the injury to the first dorsal root must have been close to its point of emergence from the inter-vertebral foramen, since there is distinct evidence of the partial paralysis of the cervical sympathetic (see Fig. 1) which receives its orbital fibres for the muscle of Muller, together with its pupil-dilating fibres, from the ramus communicans, this latter, as seen in the diagram, coming off from the first dorsal close to the inter-vertebral foramen before it has joined with the eighth cervical to form the lower trunk of the plexus. The lesion of the brachial plexus, therefore, was one which separated the nerve roots at the points indicated in the diagram, the fifth and sixth cervical roots having been torn across farther away from the spine than in the case probably of the seventh and eighth cervical and certainly of the first dorsal root. The distribution of the anæsthesia is very characteristic and is practically identical with that of a case under Dr. C. E. Beevor's charge which one of us (Dr. Purves Stewart) had the opportunity of studying over a year ago, in which, on account of brachial neuralgia, Mr. Victor Horsley excised the posterior nerve-roots from the fifth cervical to the second dorsal inclusive. After the operation there was a surviving strip of sensitive skin on the back of the upper arm, running towards the lower part of the triceps, as in our own case (see Fig. 3). In that case also the patient on passive movement of the anæsthetic limb felt as if she had a "phantom arm" whose posture never changed.



C 5, C 6, C 7, C 8, Anterior branches of the four lower cervical nerves. D 1, Anterior branch of the first dorsal nerve. A, Supplying rhomboid. B, Supplying supra- and infra-spinati. C, Supplying subclavius. D, Supplying pectoralis major. E, Supplying serratus magnus. F, Branch to pupil and orbit. G, Phrenic nerve. H, Supplying subscapularis. I, Circumflex. J, Musculo-spiral nerve. K, Musculo-cutaneous nerve. L, Median nerve. M, Ulnar nerve. N, Internal cutaneous nerve. O, Lesser internal cutaneous nerve.

The narrowing of the *palpebral aperture* and the *smallness* of the pupil on that side, with its deficient dilatation to shade, *together* with the *loss of* the *cilio-spinal reflex*, pointed clearly to a paralytic affection of the cervical sympathetic owing to interruption of the fibres of the ramus communicans of the first dorsal nerve. We were, therefore, prepared to have found on examination, ten weeks after the injury, that cocaine would fail to stimulate the sympathetic. Such, however, was not the case, for cocaine was still able to cause dilatation of the pupil and widening of the palpebral aperture. This is in favour of the statement that lower nerve roots, the second and third, according to Quain (tenth edition), also supply pupil dilating fibres to the cervical sympathetic, in addition to those supplied through the first dorsal root.

Harley street, W.

A SUGGESTION FOR A METHOD OF OPENING THE PERICARDIAL SAC, FOUNDED UPON A CASE OF PURULENT PERICARDITIS.

BY CYRIL OGLE, M.B. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL;

AND

HERBERT ALLINGHAM, F.R.C.S. ENG.,
SURGEON TO THE HOUSEHOLD OF H.R.H. THE PRINCE OF WALES;
ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

A MAN, aged 36 years, according to his wife's account suddenly complained of tightness of breathing whilst shaving himself on April 12th, 1899, and was subsequently sick. No previous illness was known of and in particular no rheumatism. He was admitted into St. George's Hospital on the 17th with delirium, dyspnœa, and orthopnœa. His face was anxious, dusky, and pale. There was nothing heard in the lungs to account for these symptoms. A large area of præcordial dulness was found extending to the left anterior axillary line and to about two inches to *the right of the sternum. No cardiac impulse was* felt and no friction was audible, although friction had been heard by a medical man before the patient was admitted into the hospital. Leeches were applied to the region of the heart and the man was bled to 10 ounces. On the 19th he was transferred to my care (Dr. Cyril Ogle). There was then considerable distress of breathing with orthopnœa, suggesting a cardiac origin; a pinched, pale face with lips slightly blue, and not in the least bloated, although both external jugular veins were very distended, not altering during inspiration, and without visible pulsation or even flicker, but they contained liquid blood. There was no œdema anywhere, nor did any subsequently appear in the slightest degree. There was no ascites, and the liver was not apparently enlarged. The area of præcordial dulness measured about eight and a half inches in width at the level of the fifth cartilage, being limited to the left by the anterior axillary line and extending upwards to the second left intercostal space. Over this area no trace of friction was at any time to be heard whilst the patient was in hospital. In the sixth space and left anterior axillary line a feeble impulse could be clearly felt and was also perceptible in a diffused fashion between this point and the sternum. There was good resonance to the bases of both lungs behind, but breath sounds were somewhat choked with medium-sized and fine râles, rather crackling in character, on the left side. On the left side near the spine, at about the middle of the lower lobe, was a patch of relative dulness. Here no alteration from vesicular breathing was to be heard and no change in voice-sounds. The pulse was steady and regular, with a small wave, but of a shooting character; the arterial tension was very low, and both ulnar and radial arteries at the wrist were plainly perceptible and flashing; in both respects the pulse closely resembled that of aortic regurgitation. The *temperature* was about *from* 100° *to* 101° F. and continued so raised. During the next three days the patient's condition remained without much change. The impulse of the heart in the anterior axillary line and inwards, however, became more evident, and the heart-sounds were heard in this region, faintly but quite clearly. The first sound was very short in character. No murmur was ever heard and no friction. There was restless, wandering delirium; simple questions were apparently grasped, but the mind then immediately wandered again.

The diagnosis seemed to be between pericardial effusion with unusual signs and that of enlarged and dilated and, perhaps, fat-laden heart, with very probably clotting in the right cavities. On the whole I was inclined to take the latter rather than the former view, for the impulse of the heart was very fairly perceptible, and right out in the anterior axillary line; the sounds were audible, the first short and snapping, as is found in dilated heart; there was no extension of dulness to the left beyond the impulse; the character of the dulness over the sternum was not the dead dulness usually associated with pericardial effusion, but rather suggested that of the heart behind the bone; the orthopnœa was distinctly of the type seen in pulmonary embolism, and together with the distension of the jugular veins, which did not pulsate, suggested clotting in the right auricle or ventricle as its cause; and there was never any friction audible, at any rate since his admission. The low tension of the pulse with its shooting character suggested pericardial effusion, and the dull patch at the back of the left lung has been, of course, observed in this condition; but the character of the pulse would be equally well explained by clotting in the right heart preventing the blood from properly reaching the left ventricle. The dull patch at the back was there if looked for, but was not very definite, and there was no tubular breathing or change of voice to suggest much compression of the lung by a distended pericardial sac. It was consequently decided not to operate but to watch the condition of the patient. The impulse on the 21st and the 22nd became even more definite, although no decrease in the size of the dulness could be made out. Delirium and orthopnœa persisted. Strychnia and digitalis with oxygen inhalations were administered. The pulse-rate continued at about 120 and of the same shooting character, but on the 23rd it rose, with a tendency to run, and became somewhat irregular; it was therefore decided to operate immediately.

Mr. Allingham accordingly made an incision along the fifth left cartilage, two inches of which he removed, and then, carefully dissecting down to the pericardium, opened the sac. Thin, non-offensive pus spurted out with considerable force and to the amount of 15 or 16 ounces. There were great masses of tough lymph in flakes adherent to the heart and lining the sac. These were as much as possible loosened by introducing the finger into the pericardial sac and firmly scraping the heart's surface where it could be reached, and thus four or five ounces were removed, but much remained at the back and base of the heart, where it could not be reached by the finger. The sac was then freely irrigated with hot water, the edges of the pericardium were sewn to the skin, and the sac was left open to secure good drainage. During the process of handling and forcibly scraping the heart with finger and sponges, there was no intermission in its beat, and the pulse, which immediately before opening the sac had been nearly imperceptible, became regular, strong, and of very fair tension and so continued as long as the heart was being cleansed. After the operation, although much better than before, it declined somewhat in strength and fulness. The man's distress of breathing was somewhat relieved by the operation, so that he was able to lie down in comfort, but he lived only for 14 hours, dying from gradually increasing weakness.

At the post mortem examination it was found that the pericardium and both lungs were strongly adherent to the chest wall. The lungs were œdematous and the left lower lobe was in a condition of partial collapse. The branches of the pulmonary artery throughout the right lung were plugged by firm ante-mortem clot. The pericardial cavity was of large size and the heart was of about normal volume, with a good thickness of muscle, which, however, was very soft. The surface of the heart was clogged by layers of coherent lymph, which also had constricted the right auricle and obliterated its appendix. The apex of the heart was much displaced downwards and outwards, as it was very firmly adherent to the lower and left part of the dilated parietal pericardium. This adhesion was evidently not of recent date; at the posterior surface of the base of the heart, also, there were some firm adhesions. The valves were healthy. The origin of the pericarditis appeared to be a collection of inspissated pus lying close to the right of the sac between it and the lung and the chest wall which was the result of a previous pleurisy. The kidneys were healthy except for cloudy swelling. The spleen was small and firm but the liver was rather large and nutmeg in character. There were a few ounces of serum in the peritoneal cavity. The other organs, including the testes, were healthy.

The difficulties in the diagnosis of the case were thus in part made clear at the necropsy. The absence of friction and the septic condition of the patient were explained by the purulent character of the effusion; the persistent impulse of the heart, and its permanent position downwards and especially outwards was accounted for by the firm adhesion of the apex to the visceral pericardium, which also explained the fact that there was no extension of dulness beyond the apex beat. The shooting character of the pulse, with empty arteries, the great dyspnœa, and eventually death, were no doubt largely due to the extensive clotting in the branches of the pulmonary artery.

Remarks.—It must be admitted that the condition of pericardial distension was in this instance left too long unrelieved. This was due in part to the difficulties in diagnosis which have been already pointed out, but still more to not realising how freely the heart can be handled, not only without harm but with positive and very evident advantage, as was shown by the remarkable improvement of the pulse in regularity, strength, and tension during the process of cleansing the heart. Since such appears to be the result, we are led to think that the heart and pericardium may perhaps more frequently and with greater confidence be subjected to surgical treatment. If this should be the case it has occurred to us that a way of approaching the heart, better than those hitherto employed, would be by opening the pericardium from below, through the diaphragm, so that a finger or sponges on holders introduced into the sac would be able to sweep round the entire heart, both back and front, over its whole extent, and thus detach and scrape away adherent masses of lymph, which are always a difficulty in the proper drainage of the cavity, and which must considerably hamper the action of the heart and more especially of the auricles. Up to the present time we have not had an opportunity of trying this method on the living subject, but we have performed the operation on the dead body in more than a dozen instances, and have found it perfectly easy to accomplish in the following way: 1. An incision of about three inches in length with its upper end at the costo-xiphoid angle is made along the lower edge of the seventh left costal cartilage; the latter is then exposed by separating the abdominal muscles from it; the cartilage can then be pulled somewhat outwards and upwards, when the fibres of the diaphragm become visible, together with the cellular interval between its attachments to the cartilage

FIG. 1.

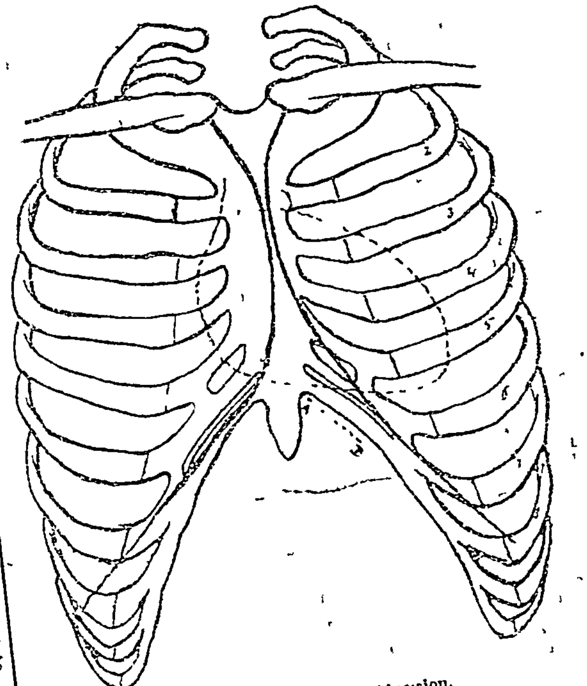


Diagram showing line of incision.

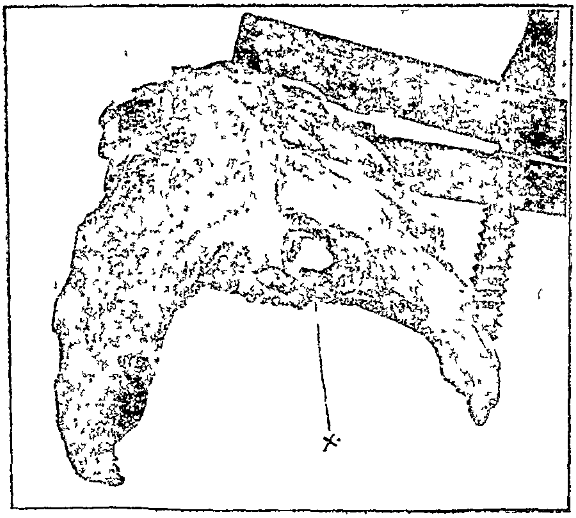
and to the xiphoid appendix 2 This cellular interval is enlarged by cutting or tearing through the muscle of the diaphragm as far as may be necessary, when a mass of fat is usually seen just above the diaphragm, in the space between the pericardium behind, the sternum in front, and the diaphragm below 3 This fat together with the diaphragm, is pulled downwards, when the pericardium presents itself and can be incised or opened up with forceps at its lowest part in front, and a large hole being made, a finger inserted can explore the heart over its whole extent, back and front, nearly as far as its extreme base During the operation the peritoneum may to a slight extent be exposed as it sweeps downwards from the under surface of the diaphragm It is, of course not injured, but is pushed aside as is done in performing a suprapubic cystotomy The superior epigastric artery is not wounded, but can be kept well inside towards the middle line, on separating the tissues after cutting through the attachment of the abdominal muscles to the seventh cartilage

The advantages of the method appear to be 1 The pleural cavity cannot be injured, as it is far away in the normal arrangement of the organs and would be still further removed in pericardial distension It would seem, indeed, that the method described is the only sure way of entering the pericardium without wounding the pleura, for the latter frequently covers the fifth and sixth intercostal spaces, even up to the sternum 2 Drainage is from the most dependent part of the sac, when the patient is half propped up, and is through a large opening not bounded by cartilage or sternum 3 Great ease is afforded for the exploration and cleansing of the heart, both back and front, to its extreme limits

Although the above operation is easy in a child or in an adult with flexible cartilages and ribs it would appear sometimes necessary, when such is not the case, to remove two inches of the seventh cartilage after the first incision, as otherwise there is not sufficient room in the xiphoid angle to make a satisfactory opening In other respects the stages of the operation are the same

Fig 1 shows the line of incision along the lower border of the seventh cartilage (A to B) It shows also the usual arrangement of the fold of the left pleura This however, would appear to vary considerably, but even in extreme cases never to reach lower than the upper border of the seventh cartilage close to the sternum It could consequently not be involved in the operation, and if it be in an unusually low position it is easily recognised by the finger and can be turned aside in an upward direction

FIG 2



Reproduction of a photograph from a dead body on which the operation was performed The parts have been dissected

Fig 2 shows the result of the operation which was performed after death and subsequently displayed by dissection No cartilage or bone was removed The upper surface of the diaphragm (A) is seen, pulled downwards, above this the parietal pericardium with the incision, through which a finger can be passed The seventh cartilage, somewhat everted and pulled upwards, is seen above The reflection of the pleural sac upon the front of the pericardium is not visible and is a considerable distance from the incision into the sac

ON THE APPLICATION OF ELECTRICITY IN MEDICAL AND SURGICAL PRACTICE[1]

BY H LEWIS JONES M D CANTAB, F R C P LOND,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT IN ST BARTHOLOMEW'S HOSPITAL

[AFTER a few introductory remarks Dr Jones said —]

It is now 150 years since the beginning of medical electricity During the whole of that time it has had to fight its way in the face of many difficulties, and the most serious of these has been the passive resistance of medical men themselves The vitality which the subject has shown under adverse circumstances is most significant Medical electricity advances steadily and the progress during the last decade has been very great The commercial application of electricity and its house to house distribution by electric lighting companies have called into existence a large number of new instruments and new methods of treatment and are helping the spread of the study of medical electricity by simplifying the means of obtaining the current when required The accumulator has been of great service by affording a trustworthy source of currents for the use of surgeons in their galvano-cauteries and exploring lamp instruments. The discovery of the x rays and their application to surgery and medicine have also done good to the cause of medical electricity by bringing electrical apparatus into more extended use, and the founding of x ray departments in hospitals gradually leads to the development of electro-therapeutic departments in places where these are not already in existence. Most of the London hospitals now have electrical departments, and these are of manifest utility. At St. Bartholomew's Hospital we have about 600 cases referred yearly to the electrical department from all quarters of the hospital, exclusive of the cases for x ray photography, the numbers of which are even greater. And the results of our treatment will compare favourably with those in any other branch of medical practice.

---

[1] Abstract of a paper read before the Institution of Electrical Engineers on March 8th 1900

It is a little difficult to speak on a medical subject before a non-medical audience without incurring the suspicions of those who are always on the alert for signs of unprofessional behaviour, and there is no branch of medical practice upon which the fierce light of criticism shines more sharply than upon medical electricity. I shall therefore have nothing to say on such matters as the relation of cases, statements of cures and so forth, which might be thought to be unsuitable to my audience, but will try to meet you on the common ground of apparatus and methods, and in particular I shall try to lay before you some of the difficulties and problems which arise in the course of our medical work in the hope that some of them may be solved by the advice and suggestions of those who are here present. From conversations which I have had at various times with engineering friends I am disposed to think that the number and extent of the applications of electricity to medical practice are not generally realised by electrical engineers. Indeed, when I have observed any reference at all to medical electricity in the proceedings of this and of kindred societies the reference has usually been one of disavowal and dislike. I therefore feel that in making the present communication to you I am undertaking the task of trying to show that electrical applications have a large and legitimate field of usefulness in medical practice; that it is quite possible to practise medical electricity without thereby becoming an outcast; and that the advertisements of electropathic or magnetic appliances do not represent the position of medical electricity any more than, shall we say, Keeley represented all that was best and truest in electrical engineering.

If what I have to say to you may seem to be about trifling matters I hope you will bear in mind that our unit is the milliampère, while yours is the kilowatt, and that the currents which we handle and use would make but a small figure if their energy were expressed in terms of horsepower. Nevertheless, in the small technical matters which have to do with the management of various kinds of small electrical apparatus the medical man requires a thorough proficiency, because it is absolutely necessary that he shall be able to make his apparatus work. On that account we may appear in certain matters to take elaborate precautions which might seem to you to be hardly necessary. With our coils and batteries we require unfailing methods for increasing or decreasing the current sent through the patient, without stops or jerks. We have to deal with the electric light mains, either direct or alternating, or both. And we have evolved for ourselves a long array of contrivances for utilising the public supplies of electricity for medical purposes. Small transformers, portable accumulators, resistances to provide slopes of potential, which can be tapped as desired for varying voltages, contrivances for using the mains for all sorts of medical purposes, are all enlisted in medical work. The statical machine is also coming again into favour and to use a statical machine one must know enough about its management to be quite sure that after a patient's arrival there shall be no awkward failure of the machine to excite. Otherwise we are likely to be condemned as not understanding our apparatus and the patient may be lost. All these little matters can only be learned gradually and through a course of failures and disappointments. And when they have been learned thoroughly they constitute a very fair claim to the title of electrician.

The use of electricity in the production of hot air baths with incandescent lamps or electrically heated coils of wire as the source of heat is a development of some promise; while in the immediate future we can see the approach of new methods of treatment by the light of the arc lamp. Each of these will demand a fresh extension of the field of electrical operations which the medical man will have to learn.

[Dr. Lewis Jones then gave a short *résumé* of the various uses to which electricity can be put from a medical point of view, laying special stress on its use for diagnostic purposes. He continued:—]

One of the most encouraging points at the present time in medical electricity is the improved quality of the scientific work which is being done in it. Last year, the French Government having declared the subject to be of public utility, a section of Medical Electricity was inaugurated at the Boulogne Congress of the French Association for the Advancement of Science. I attended the meetings of the section during the greater part of the congress and was struck by the number and high scientific quality of the communications which were made in it. It was one of the best attended sections of the whole association. France, indeed, takes a long lead in the subject of medical electricity. They have at the present time three periodicals devoted entirely to the subject and abundance of material seems continually forthcoming to fill the pages. One of them, the *Archives d'Electricité Médicale*, is quite indispensable to students of medical electricity, for, in addition to its original matter, it provides its readers with abstracts and a bibliographical index which keep one in touch with all that is being done in medical electricity all over the world.

The progress in the small matters of detail, particularly with regard to apparatus, which has taken place during the last 10 years is considerable. I say 10 years because that represents the time during which my attention has been specially directed towards medical electricity. It will be interesting to consider and compare the types of apparatus in common use to-day with those used formerly.

Electrodes.—The current is applied to the body of the patient by means of electrodes. These may be of the most varied forms, particularly with electrodes for internal applications. The cylindrical brass handles fitted with sponges and held, one in each hand, are obsolete, or deserve to be, and for most external applications their place is now taken by a plate of flexible metal enclosed in wash-leather, and a disc of metal also covered with wash-leather and screwed into a wooden handle. The former is called the indifferent electrode and serves chiefly to complete the circuit through the patient's body; the other or active electrode is the one which is manipulated and applied over the affected region. For testing the active electrode is fitted with a closing key. Examples of electrodes and other forms of medical electrical appliances are shown upon the table. Bare metal must never be allowed to touch the skin unless electrolytic or painful effects are desired. Sores are easily produced in a few minutes by a few milliampères of current if at any point the metal of the conductor touches the skin directly. For this reason some water-holding material, such as wash-leather, is always used to cover the metallic surfaces of medical electrodes.

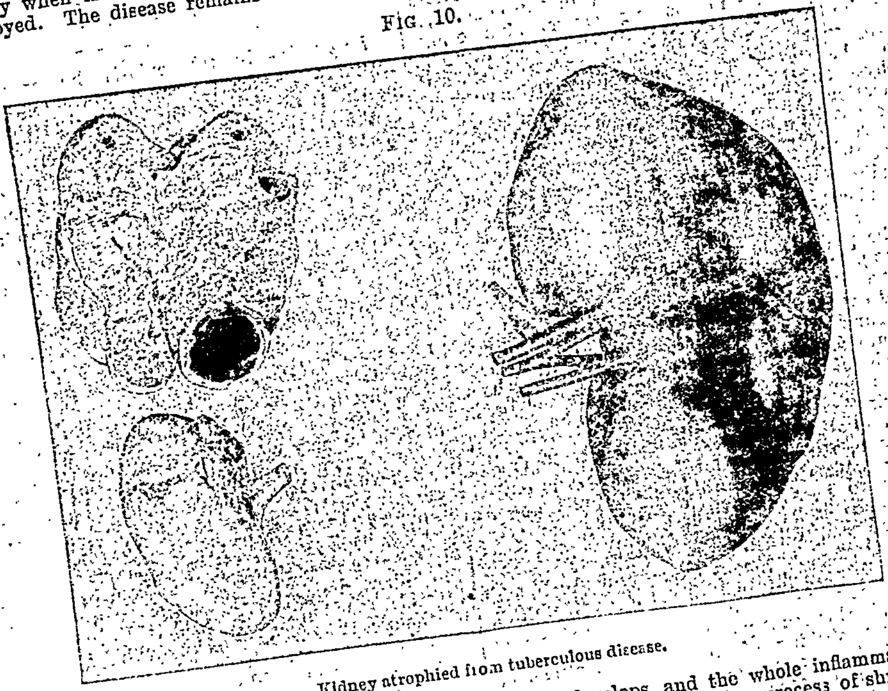
The battery.—The chief requirements in a medical cell are that it shall need no attention and will not spoil on open circuit. The past few years have seen the almost complete disappearance from medical work of open acid cells, such as the Smee cell, the Bunsen, and the bichromate cell. Formerly, when electrical treatment had to be carried out by means of ponderous oak boxes filled with cells of one or other of these kinds, the trouble and the dirt associated with them were enough to discourage all except enthusiasts. At the present day the Leclanché cell is the only type of battery which a medical man need consider, and even these are rapidly being abandoned, except for fixed installations, in favour of the modern, cheap, and convenient dry cell. With these small dry cells for currents of small magnitude and with a few accumulator cells for those medical purposes which require a current of an ampère or more, as, for example, for the heating of galvano-cauteries and the illumination of small exploring lamps, the medical man is sufficiently equipped and is no longer compelled to handle and prepare caustic solutions. Large bichromate batteries still survive in remote districts for the occasional production of large currents, but they are every year becoming less numerous, as secondary cells and the means of charging them from dynamos become more general over the country. All this simplification tends very greatly towards the increased popularity of medical applications of electricity, because, perhaps, one chief cause of its neglect has been hitherto the trouble of the management of the apparatus. The batteries needed for medical work divide themselves into two distinct classes, batteries for applying currents to patients for testing and treatment and batteries for galvano-cautery and lamp apparatus. The former is essentially a physician's battery, the latter is more for the surgeon. Most of the surgeon's requirements are met by a portable accumulator of four cells, for the little surgical lamps are for the most part eight-volt lamps, taking about an ampère, though usually they are overrun most cruelly. For galvano-cautery the currents average from five to ten ampères, but the cautery circuit has a low resistance and a pressure of eight volts is much more than is required. Sometimes the four-cell accumulator is arranged so that a switch will re-combine it as two sets of two in parallel for cautery work, or else it is left as a four-cell battery in series, the volts being expended in a resistance. For medical work a battery is fitted with from 25 to 40 small dry cells connected in series and having wires led off from them to a circle of studs from which a moving pointer takes up into circuit as many cells as are required. It is usually fitted with a milliampère meter permanently in circuit and a commutator for reversing the poles, also with an induction coil driven by a separate dry cell. The average working resistance of the human body and skin is about 2000 ohms when properly moistened with hot water. Salt or soda may be added to the water to reduce the skin resistance, but plain water is best as it corrodes the electrodes less

Next in importance to the battery of primary cells comes the induction coil. Indeed, if generality of use be considered, the induction coil should come first, as it is the form of electrical application which has the widest employment. The medical induction coil has developed in certain special directions, the chief requirement with such an apparatus being a means of careful regulation of its strength. Of the various ways of obtaining this regulation the one best suited to our purpose is the plan of using a sliding secondary coil, which can be brought close to the primary or can be removed further from it, as desired. Much has been done of late years to improve the induction coil and more has been written about the various effects to be got from coils of different sorts and construction. Attention has been given to the improvement of the vibrating spring or contact-breaker, and the best American coils are now fitted with two vibrators, one of slow speed and one of high speed. In the United States, where the construction of electro-medical apparatus has been much elaborated, it is quite customary to supply coils with several interchangeable secondaries. The same is done to a less degree by makers elsewhere. The various effects which have been ascribed to different windings of secondary are best considered as being due to the very great differences in their self-induction, according as they are made with windings of great length and many turns or of short length and few turns. The slower rise and fall of wave which is found with the high self-induction of the long coil of many windings has the effect of making the shock less sudden and less painful in its effects. So, too, in very long, fine secondaries a large part of the volts are dropped inside the coil, and the E.M.F. at the terminals, though high on open circuit, may fall almost to nothing when closed through a comparatively low resistance. On this account very long coils with very high speed contact-breakers have been much written about as affording painless currents for internal applications, but in my opinion the painlessness is due to the fact that very little current comes out of them. For practical purposes I have usually found it sufficient to use one secondary coil, which is tapped at one-third of its length and so can give long coil and short coil effects from the one instrument. Medical induction coils are not fitted with condensers. When simple stimulation is required in the treatment of a case the induction coil is probably the most convenient and cheap method of procuring it The battery current has a superiority in certain things, for example, it gives a wider range in degree and quality of stimulation; and certain living tissues respond better to battery currents slowly increased and decreased than they do to the sudden jerks of the coil. The intense effect of the coil on the sensory nerves of the skin makes it difficult to use coil currents of sufficient strength to penetrate to the deeper parts of the body, and for deep parts currents of large magnitude are necessary to make up for the weakening effect of diffusion

The strength of current used in treatment ranges between four and 40 milliampères for the most part, though smaller and larger currents are sometimes used. The larger the currents the larger should be the surfaces of the electrodes. The measurement of induction-coil currents presents difficulties which have not hitherto been surmounted, and the rough comparisons which are made by means of a scale of millimetres at the side of the sliding secondary cannot be translated into units and cannot be trusted to be alike for two consecutive days. Instruments which measure the mean current are of no use because the physiological effect does not depend upon mean current but upon the rate of change and the maxima. The use of a sinusoidal current from a dynamo to take the place of the induction coil might enable one to evade the difficulty, but the dynamo current of the mains, in certain cases at least, produces such painful skin effects as to be very unpopular with patients. It is difficult to say why this is so, but the subject wants further study. Possibly the use of condenser discharges, the condenser being automatically charged and discharged rapidly, might meet the difficulty of producing a current which would resemble that of the coil in its physiological action and would allow of measurement. I would like to ask the advice of members of the institution on this point: Would not the curve of *discharge* of a condenser have a close resemblance to the discharge curve of an induction coil? Could not one arrange a condenser of small capacity, such as a Leyden jar of diminutive size, and employ some very fine adjustment of spark gap for measurement and regulation? I have thought that in this way, using high voltages and small capacities, the disturbing factor of varying skin resistance would become comparatively unimportant.

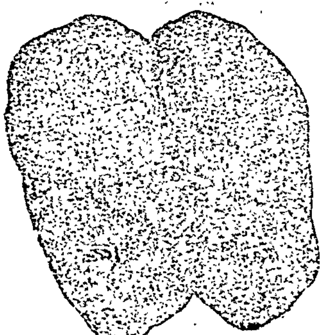
Current from the mains.—After its introduction into commerce the current of the electric lighting mains was quickly introduced into medical practice, and we make large use of it in the electrical department of St. Bartholomew's Hospital, which is connected with the mains of the City of London Electric Lighting Company. The current impulses from the alternating mains have a physiological action resembling those of the induction coil; that is to say, the effect upon nerve and muscle is to produce a permanent contraction so long as the current is applied. But it is superior to the induction coil in being a less violent stimulus to nerve and muscle by reason of the more even and gradual rise and fall of its waves. Larger currents can be borne than from the induction coil, and, judging from its effects in a long series of cases, it appears to be more thorough and more useful in its effects. Nearly all the cases formerly treated by the induction coil at the hospital are now treated by the current from the mains, the voltage being lowered to suit the requirements of the case (to about ten volts as an average), and indirectly we have gained largely in that the department is now free from the noise of eight or ten induction coils all vibrating and buzzing at once. Formerly the effect of that noise during a long afternoon was most trying. There is one marked difference in the effect of the alternating current which limits its use, and that is that if applied in the ordinary manner through moistened electrodes to the surface of the skin it has a peculiar, disagreeable, burning effect. The more thoroughly the skin is moistened the less this is noticed, and when the current is conveyed to the patient through the medium of water, as in a bath, this disagreeable cutaneous effect disappears enti[illegible] Consequently a mode of treatment by means of baths [illegible] sinusoidal current has been developed to a very con[illegible]xtent and with decided advantage to our patients [illegible] numbers of our cases are cases of paralysis of the [illegible]mbs from injury or disease of the nerves of the up[illegible]emities, and for these we use an arm-bath. The ar[illegible] is a stoneware trough, of suitable shape, having a m[illegible] electrode at each end; it is filled with warm water in [illegible] which the patient plunges the forearm and hand. The use of hot water as a medium for conveying electricity to a patient has many advantages. The current is much better borne and therefore a stronger current can be used. Manipulation of the electrodes and personal handling of the patient are done away with and the affected part is kept warm during the application. For these reasons we use it largely and I continue to advocate its use as one which again is likely to increase the popularity of electricity among the medical profession because it tends to simplify its mode of application. In addition to small local baths for parts of the body we have a large bath in which the whole of the body is animals—for example, swine plague—and never occur in man, while, on the other hand, other maladies attack the human subject while the lower animals enjoy immunity. In the guinea-pig even a few tubercle bacilli introduced into the body are certain to produce a localised tuberculosis almost invariably followed by a general dissemination of the disease. Dogs, on the other hand, are more highly resistant and a large number of bacilli must be used to produce any effect, and, as a rule, only when intra-peritoneal or intra-venous injections are employed. The disease remains localised and does not lead to a general tuberculosis. As regards susceptibility to tuberculosis certain human tissues seem to follow the course pursued in the guinea-pig while other structures offer greater resistance, analogous to that of the dog. In some structures the tuberculous process makes rapid headway, in others it remains localised for a long period, becomes quiescent, or even seems to undergo changes towards recovery. The circumstance that the tubercle bacilli may pass through the kidney and be found in the urine without producing any pathological effect illustrates the power possessed by the renal parenchyma in some individuals of resisting the injurious action of the organisms. When the lesion is limited to the parenchyma of one kidney and the bacilli are abundant and virulent rapid cell multiplication takes place, the virus speedily induces necrosis, which may extend beyond the tubercle into the vascular tissue around, inducing inflammatory changes which shut off the tubercle from the lymphatics and blood-vessels. In this way the tuberculous process may not extend into the pelvis, and in place of having an opportunity of being discharged may undergo fatty degeneration, caseation, and perhaps even calcification. Sometimes, however, even where caseation has taken place a cure is not effected, as the bacilli or their spores may still remain vigorous and active. So long as this is the case the process of caseation spreads and the tissues become infiltrated with inflammatory products. But as the organisms become less active fibrous tissue develops and the whole inflammatory focus becomes encysted. Very slowly a process of shrinking and absorption takes place. In almost all cases, however, putty-like masses or caseous nodules are left in the centre of the fibrous covering.

FIG. 10.



Kidney atrophied from tuberculous disease.

FIG. 11.



Longitudinal section of a kidney containing a caseous mass which has become encapsuled and inert.

The disease becomes quiescent so long as left undisturbed, but if injured in any way it may again become active. Tuberculous foci, even although the great bulk of the mass has become inert as a consequence of degenerative changes, almost always contain tuberculous bacilli or their spores, so that in the event of injury the imprisoned organisms may again become virulent. When a localised tuberculous centre ruptures into the pelvis of the kidney the material may become discharged by escaping externally by a process of gradual disintegration and breaking down of the tuberculous mass and evacuation of the débris; or the organ may be destroyed by suppuration and ultimately the only remnant left of the tuberculous process may be the fibrous tissue capsules.

While post-mortem examinations upon individuals who have died from other diseases provide us with illustrations of nature's methods of cure they also point out the kind of cases in which surgical intervention may be of some avail. Unilateral primary tuberculosis permits some time to elapse between the onset of the disease and the invasion to more distant parts. This period is in the great majority of cases not very long, but it is the only one in which the surgeon can interpose with advantage. A number of cases have been recorded where surgical treatment has prolonged life very considerably or where the patients have enjoyed good health for several years after the operation. The most favourable cases for operation are those in which, from the very circumstances of the case, the diagnosis is difficult and uncertain. Surgical treatment is, therefore, often not called for until the disease is advanced, or it is even postponed to a time when serious complications have set in. When, however, the physician fully appreciates the advantages of early surgical intervention and endeavours to recognise renal tuberculosis at an early stage better results will be obtained than those hitherto achieved. The medical attendant who makes an early diagnosis in a case of renal tuberculosis renders a service to his patient as valuable as that of the surgeon who at a later date performs a successful nephrotomy or nephrectomy.

Treatment.—As regards treatment tuberculous disease of the kidney may be compared to scrofulous lymphatic glands. The gland becomes infected, it enlarges, and, if not contaminated by pyogenic organisms in regular course, necrosis sets in and the whole structure becomes converted into a caseous mass, enclosed by a capsule through which the disease does not extend to the parts around although it may pass along the lymphatics to the neighbouring glands. When the whole of the lymphatic tissue is destroyed the activity of the tuberculous process becomes exhausted and a putty-like mass remains. The tuberculous glands can be easily recognised at an early stage and enucleated before the capsule has ruptured and an escape of the infective matter takes place into the surrounding parts. At a correspondingly early stage tuberculous disease is not recognisable in the kidney. It is only when the tuberculous material has broken down and the débris escapes with the urine that the true nature of the malady can be ascertained. It is true that the infective material as it escapes is very liable to produce a tuberculosis of the structures with which it comes in contact. On the other hand, the discharge of the caseous matter may be complete, and in that case healing occurs just as may happen in a lymphatic gland by the formation of granulation tissue. It is well known that where rupture has taken place the healing of a lymphatic gland is much accelerated. The danger of infection is distinctly diminished by laying the gland open and by removing its contents. So also incision, scraping, and a free drainage of the tuberculous cavity in the kidney or of the distended pelvis not only removes tension and subdues pain, but is also of value in checking the local extension of the disease and by retarding general infection.

From an examination of statistics the relative value of nephrotomy and nephrectomy in the treatment of renal tuberculosis can be roughly ascertained, but there are certain points of detail that require to be carefully considered. Take first the statistics of nephrotomies and nephrectomies collected up to 1888.[1] From an examination of the tables of nephrectomy for tuberculous disease[2] it will be observed that although the mortality is very high—namely, 36 3 per cent.—a sufficient proportion of the patients have recovered from the operation and enjoyed a prolongation of life to justify the surgeon in extending his sway where medical treatment is unavailing. The following table shows the general results:—

TABLE I.—*Nephrectomies for Tuberculous Disease.*

	Males.	Females	Recoveries	Deaths.
Lumbar	13	13	16	10 = 38 5%
Abdominal ...	—	7	5	2 = 28 6%
Totals ...	13	20	21	12 = 36 3%

Of the 33 cases operated upon in 26 the lumbar operation was performed (13 males with five deaths and 13 females with five deaths), and in seven female cases the abdominal operation was adopted with two deaths. The causes of death in the 12 fatal cases were as follows:—

TABLE II.

—	Abdominal.	Lumbar.
Shock and collapse	1	4
Septicæmia	—	1
Uræmia	1	1
Hæmorrhage	—	1
Vomiting	—	1
Cause unknown	—	2
Totals	2	10

Nephrotomy has been employed in 20 cases with six deaths (three males and three females). In six instances the minor operation of incision was followed by excision, and of these two patients died and the remaining four recovered. The following table shows the general result:—

TABLE III.—*Nephrotomies for Tuberculous Disease.*

—	Males.	Females	Recoveries.	Deaths.
Lumbar	7	12	13	6 = 32%
Abdominal	1	—	1	—
Totals	6	12	14	6 = 30%

In the fatal cases the causes of death were as follows. Two patients died from amyloid disease, one from shock following the operation, one from exhaustion, another died from an increase in the symptoms of the tuberculous disease, accompanied by epileptiform attacks, and in the sixth case the immediate cause of death is not stated. F. C. Facklam[3] included the above cases in his statistics published in 1893 and gives the following conclusions:—Nephrotomies: out of 20 cases 12 patients died, giving a mortality of 60 per cent. Nephrectomies: out of 88 cases 25 patients died, giving a mortality of 28 4 per cent. In the "Annals of Surgery," vol. xxvii., 1898, p. 18, Dr. L. Bolton Bangs of New York (referring to Facklam's statistics), in a paper on the Remote Results after Operations for Renal Tuberculosis, remarks: "This percentage should have been better and would have been if the best means of diagnosis had been used. For since 1888, the date from which I have had my cases selected, the means of diagnosis have been improved and made more accurate, especially through the perfection of the cystoscope and catheterisation of the ureters. This fact, together with the fact that in 1888 Newman's work on the 'Surgical Diseases of the Kidney' was published, led me to select the last ten years as an arbitrary period in which to begin my research. It should also be stated that all of Facklam's cases have been carefully excluded Therefore I believe that the cases which I herewith present have never before been summarised. There have been obtained from the literature 105, and through the courtesy of surgeons to whom a blank form was sent requesting details of their cases 30 cases more, making in all 135 cases Summary:—Whole number of cases 135. Deaths, one month or less after operation: exhaustion, two cases; extension tuberculosis, two cases; uræmia (42 per cent.), 11 cases; various accidents, 12 cases, deaths, total immediate, 27. Operative mortality, 27 out of 135 = $\frac{1}{5}$, or 20 per cent. Remote results: of 19 cases no record, of the remaining 89 cases, died two to three months, six cases, died four to nine months, seven cases—total, 13; immediate deaths, 27; number of deaths within nine months, 40. General mortality after operation, 40 out of 135 = 29 63 per cent. Survived one to eight years, 45 cases, or 33$\frac{1}{3}$ per cent. Prognosis good or improvement great in patients alive, one to nine months after operation, 31. Total survivors and promising cases, 31 + 45 = 76, or 76 out of 135 = 56 3 per cent. For the details of the state of health of the 35 cases who survived at least one to two years, which are instructive and in the main encouraging, I refer you to the schedule which I submit herewith and ask attention only to those which may be termed cases of prolonged survival. Of these there were ten." Dr. Bangs remarks with reference to his statistics: "The first and undoubted conclusion which they warrant is that the immediate result of the operation for renal tuberculosis in the cases in which they are indicated are brilliant. Many cases which seem to be *in extremis* and liable to speedy death from hectic, hyperpyrexia, pain, &c., have been immediately relieved, their existence made tolerably comfortable, and their lives prolonged. But a clear and positive conclusion as to the remote results has been an exceedingly difficult one to reach. ...... Still, I think the opinion, based upon such statistics as I have been able to get, is warranted that operation affords better remote results than hygiene." In many of the cases the patients recovered from the operation and lived for a few months, but in how many instances a cure in the proper sense of the term was effected it is more difficult to ascertain. While there is no reason to deny that in the kidney tuberculous disease may remain local and be completely removed by operation, the circumstance that the natural tendency of tuberculous disease is to attack simultaneously several organs, or one organ after another, renders the prospect of ultimate recovery less hopeful in this disease than in other suppurative lesions, notwithstanding that the immediate mortality from the incision is not much higher than in some of the non-tuberculous suppurative affections.

[3] Archiv für klinische Chirurgie, 1893, vol. xlv., p. 31[illegible].

Nephrotomy may be practised in the first instance if the disease is limited to a small area or has formed only one cavity which can be easily drained. In such a case hope may be entertained that no further operation may be required. But should this favourable prospect not be realised and should the wound continue to discharge, then excision of the kidney must be resorted to, otherwise the prolonged suppuration may produce amyloid infiltration of organs, including the other kidney. This danger, together with the possibility of the tuberculous disease extending to other parts, may give rise to reasonable doubt as to the wisdom of leaving the tuberculous material to separate by suppuration alone.

Various methods are adopted to facilitate the discharge of tuberculous débris. It has been proposed to empty and cleanse tuberculous pyelitis by catheterisation of the pelvis of the kidney and by washing it out with aseptic solutions. I have only employed this method of treatment on one occasion and cannot recommend it. The case was one of unilateral tuberculous pyelitis in a female. A ureteral catheter was introduced, at first every second day and afterwards daily, and the pelvis was washed out with over a pint of sterilised boric solution. For six weeks the patient stood the treatment well, but although the quantity of débris in the urine was considerably diminished no distinct improvement in the symptoms occurred and subsequently a nephrotomy was performed and the tuberculous matter was scraped out with a Volkmann's spoon. The finger should be introduced through the wound at the time of the operation and the pelvis of the kidney should be freely explored, and any caseous matter should be removed either by scraping or by the application of the cautery.

Partial excision of the kidney has been recommended in the treatment of tuberculous disease, but probably is not so suitable an operation for that malady as for lesions, such as perinephric tumours and other localised growths in the cortex of the kidney which are strictly localised or only involve a small portion of the organ.

Nephrectomy should be performed as a primary operation when the disease extends over a large area and where there is little hope of success by incision and drainage, also in cases of strumous disease where nephrotomy has previously been performed but in which a sinus and discharge persist. Where there is no reasonable prospect of saving useful renal tissue or attaining comparatively rapid spontaneous evacuation nothing can be gained and much may be lost by delay; therefore, if the general health of the patient be such as to permit nephrectomy being performed it should be resorted to at the earliest possible date—indeed, whenever it has been shown that the disease is limited to one side.

In many instances the advanced condition of the tuberculous lesion prohibits all operation, but when the nature of the case is discovered early and the disease is limited to one side an incision should be made and the condition of matters explored. If the disease can be removed without excising the whole organ so much the better, but if on examination several centres are discovered, or if the disease is extensive, the kidney should be excised at once. Undoubtedly primary nephrectomy is the favourite operation and the one most likely to effect a permanent cure. Although drainage alone, or even with thoroughly scraping out the tuberculous lesions, gives relief, it is often only short-lived and the ultimate result proves unfavourable. In those cases in which operative interference is considered inadvisable the treatment must be symptomatic. The general constitutional treatment of renal phthisis belongs properly to the domain of the physician rather than to that of the surgeon, who can practically do nothing in the way of soothing local symptoms by instrumentation. On account of the great tendency of the urine to become alkaline and to decompose, washing out the bladder is n most instances contra-indicated. The internal use of boric acid, salol, or benzoate of ammonia frequently gives considerable relief to vesical irritation; the administration of antipyrin combined with extract of hyoscyamus has a similar effect. Strangury may be alleviated by the administration of preparations of opium per rectum or by the employment of warm sitz baths, and when the urine has become alkaline calomel administered by the mouth has also a very beneficial effect. Strict attention must be given to all hygienic details, to the careful regulation of diet, and if possible recourse should be had to a dry and elevated health resort.

Glasgow.

COMPLETE OSSICULECTOMY (REMOVAL OF REMAINS OF DRUMHEAD, LARGER OSSICLES, AND EXTERNAL ATTIC WALL) IN CHRONIC OTITIS MEDIA,

WITH ANALYSIS OF 50 CASES.

BY R. LAKE, F.R.C.S. ENG.,
SURGEON TO THE METROPOLITAN EAR AND THROAT HOSPITAL;
ASSISTANT SURGEON TO THE ROYAL EAR HOSPITAL, ETC.

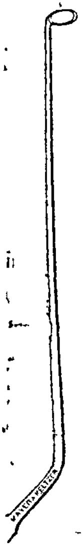
REMOVAL of the remains of the tympanic membrane and of the larger ossicles has been a recognised mode of treatment for chronic suppurative disease of the middle-ear for some considerable time. The results of continental surgeons have been reported and at various times papers have appeared in this country, of which one by Mr. A. Cheatle is fresh in the minds of many as a particularly useful expression of the opinions of a number of leading specialists at home and abroad. In none of the papers which have appeared of recent years is there any tabular list of cases by which one can estimate either the value of the operation or the class of cases for which it should be done or its results as regards the hearing power.

The table which accompanies this note shows some of these points. Thus it is seen to be a very successful operation, that it is entirely free from danger to health, and, finally, that the hearing is often improved and rarely, if ever, diminished. But perhaps the point of all which will be of most general interest is the probability of cure; this will be within a little of the results of the 50 cases following. It is not all cases of suppurative otitis media that yield to the operation. Unfortunately, many, and especially amongst the class from which hospital patients are drawn, require the radical operation, foremost amongst these being those accompanied by cholesteatomata of the attic and cases of destruction of the wall of the meatus in the posterior surface. In these cases the surgeon should, in my opinion, perform the operation, following it up later with the larger should it prove insufficient. I cannot go so far as some of our continental *confrères* who use it even in cases which threaten graver mischief.

The indications for the operation appear to me to be divisible into two main subdivisions—those for the cure of chronic suppurative otitis and those for the improvement of hearing after the cessation of discharge. It is difficult, and indeed impossible, to place any time-limit as to how long chronic otitis media suppurativa will remain harmless even when unaccompanied by any other symptoms. As a general guide one may say that this duration is directly affected by the effects of treatment and by the situation of the perforation. An uncomplicated otorrhœa which has resisted all forms of treatment for six months is certainly a case for ossiculectomy. This becomes more imperative when the perforation is situated in the attic or upper posterior segment of the drumhead. A perforation in either of these situations is more surely indicative of a lesion in some part of the ossicular chain; for instance, pus pouring down over the long arm of the incus and head of the stapes first destroys the joint and then the bones to a variable extent. Again, these perforations, if they heal, as they often do under appropriate treatment, are usually accompanied by a marked diminution in the hearing power if the suppuration is of long duration, which loss can often be remedied to a large extent by a careful operation. A very useful practical test has been formulated by Mr. A. Cheatle—viz., if in any case it is desirable to ascertain the continuity or discontinuity of the ossicular chain the membrana tympani is gently stroked with a Hartmann's probe; in the first instance this is *heard and felt*, in the second it is *felt* only. When the attic is the seat of cholesteatomatous degeneration it is especially imperative to do more than simply remove the ossicles; the outer attic wall must also be removed. This removal of the outer attic wall is now becoming considered as an integral part of the operation, though in the cases quoted it was not done, as I was only led to adopt it later from its good results in the hands of others, but I now consider it of such importance that I do it in all cases.

The condition of the ossicles—In none of my cases in which the operation in question has been performed for chronic suppurative disease have the ossicles been intact Either the head of the malleus, its long process, or some part of the incus has been destroyed. Of the latter bone the short process longest resists the corroding action of the pus, though frequently the whole incus is destroyed, and often the head and crura of the stapes also. More rarely the incus and malleus are firmly ankylosed, or the much thickened capsular ligament holds together two useless remnants. From this one sees that the chain is never intact in old-standing cases. The tympanic membrane is thus cut off from all communication and connexion with the labyrinth and can no longer perform its functions; in fact, it often becomes both an impediment to the inward passage of sound and the outward flow of pus. This is an additional argument for operative interference of some kind.

FIG. 1.



Author's attic (or incus) curette.

The indications for the operation have already been alluded to. They are briefly as follows. 1. Intractable disease of the attic with a perforation in Shrapnell's membrane, especially if accompanied by definite caries or deafness. 2. Intractable disease with perforation in the posterior superior quadrant. 3. Intractable disease with considerable destruction of the membrane in any other situation. 4. Residual deafness after suppuration without nerve deafness. Any more serious condition becomes a case for the radical operation, but in the foregoing there is, in my opinion, justification for attempting to avoid more serious measures The operation itself is so well known and so clearly described in text-books that all I can do here is to emphasise the necessity of removing the anterior attic wall. This may be done with any of the cutting forceps as Krause's, or by means of Cheatle's burr, which enables a more radical operation to be done. The use of my crotchet-shaped curettes, which were first recommended by me in 1896 as a means of removing the incus and clearing out from the attic granulation tissue and detritus, has much simplified the hitherto difficult task of removal of the incus. By its use the smallest particle of a necrotic incus can be removed with certainty from the iter ad antrum. The instrument in question, of which an illustration is given, is introduced into the attic after removing the malleus; it thus occupies the place vacated by the head of that bone. The handle is then rotated forwards and grips the incus or what remains of it, and by a forward and downward motion the bone is either dislocated into the tympanum or brought out in the loop of the instrument. As a last

REMARKS.

CASE 1.—Vertigo occurred on syringing before the operation.
CASE 5—There was vertigo for two weeks after the operation
CASE 6—Hæmorrhage occurred before the operation
CASE 12.—Vertigo was present for three weeks after the operation
CASE 13—The stapes, with the exception of the footplate, was also removed
CASE 17—Recurred and again discharge ceased
CASE 26.—Recurrence took place and again ceased
CASE 35.—There was vertigo one week after the operation.
CASE 40—The hearing was fair Facial palsy was present before the operation, but recovery occurred later
CASE 44—There was cholesteatoma of the attic.
CASE 47—Vertigo was present for ten days after the operation.

precaution the cavum is thoroughly cleansed with Lister's strong solution, a precaution which contributes materially to the ultimate success of the operation. Transient vertigo occurs in a small proportion of cases, but septic absorption has never been reported.

These 50 cases are almost equally divided amongst the sexes, but nothing can be deduced from that fact, as the proportion of otorrhœas in the sexes is fairly equal. As to cure, no less than 42 were cured, although three had temporary relapses and in several of the remaining eight the patients disappeared before a cure was effected and some may now be well if all are not. Improvement was noted in the hearing power in 21 cases. In three cases hearing returned to normal, in four cases it was very much improved, and in the remaining 14 the improvement was sufficient to be appreciated by the patients and their friends and was demonstrated as well by careful tests. The right ear was the seat of disease in 29 cases and the left in 21 cases The average age of the patient was 22·4 years and the average duration of the disease was 13 years. From this table can be derived information on all points save as to the time that should be allowed to pass before taking some radical step to check the disease, and the surgeon must rely upon his own judgment in this matter rather than upon any written rule.

Harley street, W.

A CASE OF

GUNSHOT WOUND OF THE ABDOMEN WITH INJURY TO THE INTESTINE;

RECOVERY WITHOUT OPERATION.

By O. REISSMANN, M.A., M.B. CANTAB, B.Sc. LOND.,
CIVIL SURGEON AT NO. 1 GENERAL MILITARY HOSPITAL, WYNBERG, CAPE TOWN.

THE patient, a well-built man, aged 31 years, was shot by a Mauser bullet in the engagement at Elandslaagte on Oct. 21st, 1899 The shot was fired from a distance of about 200 yards. The patient at the time was advancing in the direction of the enemy at a "double" when he felt a burning sensation in the right hypochondriac region which a minute later grew into a severe griping pain. Becoming immediately faint, though without loss of consciousness, he fell and at once vomited about half a pint of nearly pure blood. The pain, which became still more severe, was confined to a small roughly circular area three inches in diameter with its centre over the inner extremity of the ninth right rib in front The patient lay on the ground for about 20 minutes, during which time there was considerable hæmorrhage from the wounds. He was then dressed by a comrade, the dressing consisting of a puttee unwound from the patient's leg and which had been worn for several days and through heavy marching. This rude dressing was placed in immediate contact with the wounds and was wound several times round the body, nor was it disturbed for four days. After this first dressing the patient lay on the field for five or six hours and was then carried sitting in a chair to a farmhouse where he remained in a sitting posture for two days, when he was removed by train to the field hospital at Ladysmith. Here on Oct. 25th the first dressing, which was soaked through with blood (now dry), was replaced by one of cyanide gauze. The patient remained at Ladysmith for eight days, during which time he was kept on liquid diet; he was then removed to Pietermaritzburg where the wounds were dressed for the third time. From Pietermaritzburg, after a week, he was removed here. Ten days after the injury he was given solid food (meat and vegetables). There was never any universal abdominal pain nor was there any distension of the abdomen. The patient did not micturate for 18 hours after the injury and he stated that his urine then was dark in colour; it was not ascertained whether it contained blood. The bowels were not opened for two days and the patient stated that the motions contained much blood. He had not taken medicine.

On Nov. 17th the patient was up and about and in his usual health. Over the inner end of the ninth rib on the right side in front and half an inch outside the nipple line was a regular-shaped oval scar with a long diameter for one-third of an inch, indicating the point of entrance of the bullet. There was a similar scar, identical in size and shape, situated half an inch above the right iliac crest behind and four inches to the right of the vertebral spine. The wounds had healed without suppuration and there was no thickening about them. The abdominal respiratory movements were free. The liver dulness, which commenced at the sixth rib, extended to the costal margin, and the edge of the liver could just be felt below the ribs on deep inspiration. The entrance wound above described was half an inch above the lower limit of the liver dulness. There was no abdominal tenderness or induration and no dulness in the flanks.

There can be no doubt that the bullet penetrated the peritoneal cavity, possibly perforating the liver and, I think, certainly penetrating some part of the alimentary canal, either the pyloric end of the stomach or the ascending colon. It is impossible to join the points of entrance and exit of the bullet by a right line which does not also pass through the peritoneal cavity. In itself, of course, this affords no proof that the bullet must have penetrated the peritoneum, since it is well known that by impact with a bone bullets sometimes deviate considerably from their course and occasionally even pass a considerable distance round the body beneath the skin before again emerging. In such cases also a hard cord can often be felt following the track of the bullet beneath the skin from its point of entrance to that of its exit. No such hard cord was present in this case 18 days after the injury when he was first seen by me. But the fact that the injury was immediately followed by hæmatemesis and shortly also by melæna is sufficient to prove that the intestine was injured and in all probability perforated. I do not think that the kidney was injured, and the dark colour of the urine which has been referred to was probably due to concentration and not to admixture of blood (the patient was suffering from shock at the time).

The case is of importance from the point of view of treatment, for we are taught that cases of gunshot wounds of the intestine should be submitted to immediate laparotomy without waiting for symptoms to develop. That is to say, in war time such cases would require to be operated upon at the field hospital, which is stationed near the fighting line and moves with it, and where the conditions for performing so serious an operation as a laparotomy for intestinal suture are by no means good.

Here, then, we have a case where the risks of peritonitis would seem to have been of the greatest, for the peritoneal cavity was in direct continuity both with the exterior of the body by a wound covered with a dressing hardly likely to be sterile or antiseptic and also with the interior of the gut, and yet peritonitis did not supervene and the patient made an uninterrupted recovery.

From observations made upon a single case one would not, of course, propose to draw general conclusions. Nevertheless the statement that all perforated wounds of the intestine must be dealt with by an immediate laparotomy would appear to be somewhat too rigid and to require modifying.

Wynberg.

CARDIFF SEAMEN'S HOSPITAL.—The net proceeds of the bazaar recently held in aid of this institution were £4276.

CORNGREAVES HALL RETREAT.—This retreat for inebriate women of any religious denomination voluntarily submitting themselves to the treatment and regulations of the institution is in Staffordshire, between Halesowen and Old Hill. The nearest railway station is Old Hill on the Great Western Railway, distant a mile and a half. Cradley and Halesowen stations are also convenient. The retreat is managed by a committee of ten ladies and nine gentlemen, all of whom are members of the Worcester Diocesan Church of England Temperance Society. Applications for admission may be made to the lady superintendent, Corngreaves Hall, Cradley Heath, or to the secretary of the Worcester Diocesan Church of England Temperance Society, Temperance Institute, Corporation-street, Birmingham, or to the honorary secretary of the Retreat, Mr. J. H. Broscomb, 571, Moseley-road, Birmingham. No person will be admitted for less than 12 months except under special resolution of the committee, and patients are strongly advised to enter for two years. Patients under special circumstances may have their children under the age of 12 months with them. The terms are £1 1s., or 10s. 6d., or 5s. per week according to class of patient. The age limit is from 20 to 45 years.

KENSINGTON INFIRMARY

A CASE OF TRAUMATIC TETANUS WITH RECOVERY

(Under the care of Dr H P POTTER)

WE have published within the last year in THE LANCET[1] many cases of tetanus, in some of which the antitoxin has been employed while in others the treatment has mainly consisted in giving sedatives When the results are examined it must be acknowledged by any unbiased critic that the antitoxin treatment has not fulfilled the expectations to which its first successes gave rise When injected subcutaneously it seems to benefit those cases only which are not very acute or very severe and even when injected under the dura mater or intra cerebrally it does not appear to be much more efficacious In a paper on the intra cerebral injection of the antitoxin 13 cases are collected, and of these six recovered, but even with this method an early diagnosis is of the greatest importance in order that the treatment may be commenced before the nerve centres have been much involved The efficacy of tetanus antitoxin is readily demonstrable *in vitro*, and in the body also the antitoxin can destroy the toxin if it can meet the toxin before the latter has reached the nerve cells with which it enters into a firm union The intra cerebral injection is also not without obvious risks of its own and one case has been recorded[3] in which death occurred from two abscesses in the brain eight weeks after the last intra cerebral injection The plan of treatment by sedatives though of distinct value in mild cases appears to be of little use in severe attacks yet in some cases as in that recorded below, it is efficacious Krokiewicz has published[4] three successful cases of the treatment of tetanus by the injection of brain emulsion but the cases are too few to justify the expression of any definite opinion in its favour A treatment which deserves to be more extensively tried is that introduced by Baccelli This consists in the subcutaneous injection of a 2 per cent solution of carbolic acid The total quantity of phenol injected must be large even as much in some cases as 35 centigrammes per diem As Ascoli[5] points out this method of treatment must be accompanied by thorough local disinfection, attention being also paid to the support of the patient's strength Ascoli has collected 33 cases of this treatment and of these only one patient died, and in that case no more than 23 centigrammes of phenol were injected in the three days during which the treatment lasted In no instance were any signs of poisoning produced This method certainly deserves a more thorough trial than it has hitherto had in this country The mortality from tetanus is very high and seems to depend chiefly on the length of the incubation period The following figures have been given[6] in cases in which the incubation period was less than eight days the mortality was 91 per cent, when between eight and 14 days the death rate was 80 per cent, but when longer than a fortnight the mortality was only 52 per cent

A man, aged 45 years, was admitted into the Kensington Infirmary on Dec 29th 1899 for stiffness in movement of the lower jaw of four days duration He stated that he had been drinking heavily and walking about the country with badly fitting boots 14 days before admission a nail had pricked his heel causing a sore When admitted the first thing which attracted attention was well marked risus sardonicus with fixation of the lower jaw, which could be forced open to the extent of half an inch The muscles of the neck and back were firmly contracted, and such was the stiffness of the limbs that the patient could do nothing for himself with the arms nor could he stand upright There were occasional spasms of the face and trunk with profuse sweating and much distress An excoriated blister of the size of a shilling with an inflamed area around was present on the heel, there was also slight excoriation of the arm and knee, to these carbolic dressings (1 in 40) were applied During the evening he had three spasmodic attacks, in which the angles of the mouth were retracted and the alæ nasi were dilated The patient was removed to a quiet darkened room and every four hours was given 15 grains each of chloral and potassium bromide, which he swallowed with a sudden gulp On the following day in consequence of three severe paroxysms, the chloral and bromide were increased to 30 grain doses every four hours From this time there were no spasms although the dysphagia continued, but in spite of this the nurse induced the patient to take a fair quantity of milk Constipation, which was continuous throughout the illness was relieved with calomel and enemata the temperature and urine were normal An attack of delirium tremens ensued on the 31st and lasted for four days During this complication the pulse on one occasion became almost imperceptible and the countenance was alarmingly livid The medicine was discontinued on Jan 4th 1900 but it was necessary to repeat it two days later for a relapse in the fixation of the jaw From this date the patient made an uninterrupted recovery and suffered only from loss of coordination in the lower limbs with exaggerated patellar reflex

Remarks by Dr POTTER —The report of a case of tetanus under the care of Dr W Dyson interested me exceedingly as the above case has lately been treated for the same disease with similar drugs and a successful result I may also mention that a case of acute tetanus following a small puncture of the foot by a nail in the boot was treated in this infirmary in 1897 The man died and at the inquest the somewhat paradoxical but true verdict was returned, 'Asphyxia following injury from a nail

SOUTH DEVON AND EAST CORNWALL HOSPITAL

A CASE OF INTESTINAL OBSTRUCTION DUE TO THROMBOSIS OF SOME OF THE MESENTERIC VESSELS, LAPAROTOMY DEATH, NECROPSY

(Under the care of Mr C WHIPPLE)

MR TREVES in his work on 'Intestinal Obstruction (p 447) points out that thrombosis of the mesenteric arteries produces symptoms which are as a rule more acute than those manifested when the corresponding veins are involved Recovery in acute cases is only probable if an early laparotomy be performed

A man aged 48 years, was admitted into the South Devon and East Cornwall Hospital on Oct 22nd 1899 He had been in the hospital 12 months previously under the care of Dr Lawrence Fox with symptoms of Bright's disease and delirium when he was found to have albuminuria and retinitis The present illness began on Oct 19th when he had pain in the abdomen and nausea but he went about his work as usual On the 20th the pain and nausea continued and on the 21st these symptoms became worse and he passed no urine On the morning of the 22nd he called in Dr C J Cooke who passed a catheter but found no urine in the bladder and as the man's condition was bad and his abdomen was distended and painful he sent him to the hospital

On admission the patient was found to be a stoutly built man of bloated aspect He was suffering from nausea and vomiting of greenish fluid and from constipation since Oct 20th The abdomen was moderately distended and dull from the presence of fluid in both flanks, and it presented an indefinite fulness and tenderness in the hypogastric region Under the influence of gin he passed eight ounces of urine in the evening and seemed to be somewhat better. On the 23rd he passed more urine, but was still suffering from nausea and vomiting of greenish fluid. Compound powder of jalap was given in the morning, and later in the day an enema containing castor oil was administered, but with no result. At 2 A.M. on the 24th Dr. H. W. Webber, who was called by the house surgeon to see the patient as his condition was rapidly becoming worse, found him to be dusky in colour, with a feeble intermittent pulse of 140 to the minute and with a distended abdomen; he continued to vomit.

[7] THE LANCET Feb 24th, 1900 p [illegible]

Ether being cautiously administered a two-inch incision was made in the middle line below the umbilicus. On opening the peritoneal cavity some chocolate-coloured fluid escaped and the presenting small intestine was seen to be deeply congested and distended. Two fingers inserted into the wound felt distended bowel everywhere and towards the pelvis an indefinite nodulated mass. The patient's condition being extremely bad, one of the distended coils of bowel was brought up to the wound and fixed there by a horseshoe shaped flat metal rod (designed for this purpose by Mr. Hamilton Whiteford) and the bowel was incised, when gas and a little fæcal matter escaped. A large rubber drainage-tube was fixed in the enterotomy wound, dressings were applied, and the patient was removed to his bed in a moribund condition. The operation only lasted a little over 15 minutes. On recovering from the anæsthetic he became violently delirious and could with difficulty be kept in bed; he then sank rapidly and died at 5 A.M.

Necropsy.—At the post-mortem examination, which was held on the same day, it was found that a portion of the ileum, 38 inches in length, was deeply congested and in places pulpy and becoming gangrenous. Two sections, each of about four inches long, were adherent along this length. The bowel wall was thickened and nodulated with blood-vessels distended with firm clot. The portion of mesentery corresponding to the affected bowel showed many vessels filled with firm dark blood-clot. Very little fæcal matter was contained in the bowel. The thoracic organs were not examined.

Remarks by Dr. WEBBER.—The specimen was shown at a meeting of the Plymouth Medical Society and in the discussion as to treatment in these cases the opinions were expressed: (1) that if the portion of bowel and mesentery involved is not extensive and the patient's condition is good the affected area should be excised and junction should be effected by immediate suturing or with the aid of some mechanical support such as Murphy's button; and (2) that if the amount of bowel and mesentery involved is extensive or the general condition of the patient is serious the affected area should be brought up to the abdominal wall and fixed in the wound, and the healthy bowel immediately above should be opened and drained until such time as a secondary resection of the diseased area becomes feasible. For permission to publish the notes of the above case I am indebted to Mr. Connell Whipple, senior surgeon.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The Results obtained by Injecting β-amido-butyric Acid into Animals.—Observations on the Excretion of Nitrogen in Rheumatoid Arthritis.—Experiments on the Rootlets of the Ninth, Tenth, and Eleventh Cranial Nerves in Cats and Dogs.—Demonstrations of Various Experiments.

A MEETING of this society was held on March 6th at the Laboratories of the Royal Colleges of Physicians of London and Surgeons of England, Victoria-embankment, Mr. PEARCE GOULD, the Vice-President, being in the chair.

Dr. KARL GRUBE of Neuenahr communicated the Results on Animals which he had obtained by Injecting β-amido-butyric Acid, the experiments being undertaken to obtain some information on the causes that produced diabetic coma He first discussed the various theories that had been brought forward to explain the occurrence and symptoms of diabetic coma, and then directed attention to a paper by W. Sternberg which was published a short time ago in the *Zeitschrift für Klinische Medicin*, in which on theoretical grounds as well as on experimental evidence β-amido-butyric acid had been shown to be the probable cause of diabetic coma. By modifying the experiments of Sternberg Dr. Grube succeeded in producing in cats a condition very like the typical diabetic coma He not only got deep narcosis but also an alteration in the respiration analogous to that found in diabetic subjects and which had given the typical diabetic coma the name of "dyspnœic coma." He also succeeded eight times out of nine in demonstrating the appearance of diacetic acid in the urine, and in four experiments acetone could also be demonstrated. According to his experiments he was therefore able to produce by injecting β-amido-butyric acid (1) coma; (2) a respiration very similar to that appearing in diabetic coma; and (3) to show the presence in the urine of some of those substances that are found in the urine of comatose diabetic patients. Dr. Grube therefore concluded from his experiments that β-amido-butyric acid might possibly be one of the substances, if not the substance, that produced diabetic coma.

Dr. W. BAIN described a typical case of Rheumatoid Arthritis occurring in a young man in which he made a quantitative examination of the urine for seven consecutive days, the patient being on a fixed diet. The average daily amounts of the constituents estimated were as follows: urea, 18 856 grammes; uric acid, 0·266 gramme; phosphorus pentoxide, 0·986 gramme; alloxur bases, 0 033 gramme; and ammonia, 0 397 gramme. Lactic acid was not detected. It would be observed that there was a diminution in the excretion of uric acid and phosphates.

Mr. A. W. CADMAN described Experiments on the Rootlets of the Ninth, Tenth, and Eleventh Cranial Nerves in Cats and Dogs, the general arrangement of the rootlets in these animals being in three main bundles—viz, (1) an upper bundle consisting of two large rootlets—the so-called "glosso-pharyngeal"; (2) a middle bundle consisting of four or five smaller rootlets—the vagal; and (3) a lower bundle consisting of two well-marked rootlets—the accessory, these bundles, however, being often further subdivided into smaller strands. Two series of experiments were described. The first series was carried out by direct electrical and mechanical stimulation of the divided rootlets in animals which had been bled and the bone then rapidly removed. These experiments were on the palate, pharynx, and œsophagus, the fibres to the œsophagus and levator palati being found in the upper bundle, and those to the constrictors of the pharynx in the upper bundle, and the upper rootlets of the middle bundle. The second series of experiments was carried out by reflex excitation of the central cut end of the right vagus, after division of the left rootlets, in living animals whose carotids had been ligatured. These experiments were on (1) cardiac inhibitory fibres which were shown to be in the lower rootlet of the lower bundle; and (2) respiratory (Hering Breuer) fibres which were found in the lower rootlet of the upper bundle.

Dr. T. G. BRODIE and Dr. W. E. DIXON performed an experiment demonstrating the Action of Certain Drugs on the Pulmonary Circulation and the Bronchial Muscles. The injection of suprarenal extract gave rise to an increase of blood-pressure and to congestion of the lung. The injection of muscarine caused a spasmodic condition of the bronchial muscles and the demonstrators stated that pilocarpin had the same effect. On the other hand, it was found that atropine counteracted the effect thus produced, and they had also found that urethan had the same antagonistic action to muscarine and suggested that this latter drug might be of service in cases of asthma.

Dr. PAVY, Dr. BRODIE, and Mr. T. G. SIAN demonstrated the Effect of Phlorizin in Producing Glycosuria in an Artificially Perfused Kidney. It had previously been shown that the injection of phlorizin into the renal artery of one kidney gave rise to an increased flow of urine from that kidney and to the presence of sugar and that the other kidney was only affected later when the drug passed into the general circulation. The experiment performed showed that in an extirpated kidney in which the circulation was maintained the injection of phlorizin gave rise to the presence of sugar in the urine excreted. The sugar was produced from a proteid molecule and the effect of the drug was to allow it to pass through the epithelium of the kidney.

Dr. PAVY then demonstrated the Production of Glycosuria by Exalted Respiration. He said that he had shown this some years ago, but he had not then the convenient apparatus for maintaining exalted respiration that he now had. In an animal in which exalted respiration had been kept up for some time he demonstrated the presence of sugar in the urine and showed at the same time, by the red colour of the liver, spleen, and vessels of the intestine, that the blood was in a supra-oxygenated condition.

Dr. **BRODIE** demonstrated the action of Diphtheria Toxin on the Spleen. He said that he had previously shown that the diphtheria toxin produced paralysis of unstriped muscle. With the spleen in an oncometer he showed that the first effect of injecting five cubic centimetres of a weak diphtheria toxin was a constriction of the vessels of the spleen This was rapidly followed by a relaxation, then by an alternate relaxation and contraction, and, lastly, there was complete paralysis of the spleen, and the further injection of toxin produced no constricting effect.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Urotropine as a Urinary Antiseptic.—Intestinal Obstruction.—Contracted Pelvis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 2nd, Dr. **GORDON BLACK**, the Vice-President, being in the chair.

In the absence of the President Dr. **BLACK** alluded to the loss sustained by the death of Mr. Thomas Scattergood, dean of the medical school and a past President of the society.—A vote of condolence with his family was passed.

Mr. **P. J. CAMMIDGE** described in detail a number of bacteriological and chemical experiments which he had carried out in his investigations on the manner of the Excretion of Urotropine in the Urine and the Cause of the Antiseptic Properties possessed by the Urine of the Patients taking the Drug. Mr. Cammidge pointed out the very marked inhibitory power which it showed over the growth of the typhoid bacillus and urged that urotropine should be used in all cases of enteric fever to prevent dissemination of the bacilli by the urine and to avoid the cystitis, &c., liable to complicate the disease.—Dr. **GORDON BLACK**, Dr. **T. CHURTON**, and Dr. **E. F TREVELYAN** took part in the discussion which followed and Mr. **CAMMIDGE** replied.

Dr. **BASIL HALL** (Bradford) read the reports of two cases of Intestinal Obstruction caused by Meckel's Diverticulum. The first case occurred in a boy, aged 15 years, and was quoted as a typical instance of strangulation by a band, the *onset and symptoms being of an acute character.* The abdomen was opened in the right iliac region and the diverticulum was removed, the patient making an uneventful recovery. The second case was that of a boy, aged three years, and was peculiar on account of its very gradual onset. For a period of four days the child suffered from constipation and occasional vomiting, but continued to play about the house. On the fourth day some abdominal distension appeared, the child passed very rapidly into a state of collapse, with greatly increased distension and signs of peritonitis. The abdomen was opened in the middle line and a Meckel's band was found constricting a loop of ileum. The loop was in a condition of volvulus, evidently of recent formation, thus accounting for the onset of acute symptoms on the fourth day. In both cases the diverticulum was attached to the root of the mesentery near its termination —Dr. **T. W. GRIFFITH** and Mr. **B. G. A. MOYNIHAN** discussed the paper and Dr. **BASIL HALL** replied.

Dr. **J. B. HELLIER** described a case of Kyphotic Pelvis in which the transverse diameter of the pelvic outlet was reduced to 1⅜ inches. The patient was 4 feet 8 inches in stature and had lumbo sacral kyphosis due to injury in infancy. She was admitted into the Leeds Infirmary on Christmas Day after having been 24 hours in labour. The uterus was in a state of tonic spasm and the head was impacted against the ischial spines. She was delivered by craniotomy. Dr. Hellier showed drawings and photographs of the case and described the relation between angular curvature and pelvic deformity.

The following cases, specimens, &c., were exhibited,—

Mr. **T. R. JESSOP**: A case of Aneurysm in the Neck treated by Ligation of the Common Carotid. The patient was shown.

Dr. **E. O. CROFT**: Uterus removed for early Columnar Carcinoma commencing at the Internal Os, with Microscope Specimens.

Dr. **E. WARD**: (1) Malignant Disease of the Rectum; (2) Biliary Calculi removed from the Common Duct; and (3) Leucocythæmic Spleen.

Dr. **T. CHURTON** and Mr. **H. LITTLEWOOD**: A case of Lumbar and Subphrenic Abscess bursting through the Lung. Operation was performed with recovery.

Mr. **P. J. CAMMIDGE**: (1) Growth of the Œsophagus (Dr. Chadwick's specimen); (2) Section of Tuberculous Intestine showing Bacilli; and (3) Fibrinous Pericarditis.

Mr. **H. LITTLEWOOD**: (1) Three-quarters of a Stomach removed for Diffuse Malignant Growth (Columnar Epithelioma) involving the Great Curvature, together with some Enlarged Glands. The ends of the stomach and duodenum were closed and the jejunum was attached to the stomach by means of a Murphy's button. The patient was a man, aged 53 years. He suffered very little from shock after the operation. He did well for three days He died on the seventh day from peritonitis. The part of the stomach near the button was soft and sloughy and here the contents had leaked into the peritoneum. (2) The Bladder and Kidneys *from a case of Enlarged Prostate.*

Dr. **E. F. TREVELYAN**: (1) A specimen of Atheromatous Endocarditis of the Aortic Valves. Two of the cusps showed firm cohesion with a calcareous mass in the line of union. There were early adhesions between one of these cusps and the remaining cusp. (2) Punctiform Hæmorrhages with Erosions in the Mucous Membrane of the Stomach. Both these specimens were taken from the body of a diabetic patient, aged 56 years.

Dr. **T. CHURTON**: (1) A case of Biliary Cirrhosis in a girl aged eight years; and (2) a case of Gonorrhœal Rheumatism of the Ankle-joint.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS

Pathological Ovary—Clinical Report of the Rotunda Lying in Hospital.

A MEETING of this section was held on Feb. 9th, Dr. **A. V. MACAN**, the President, being in the chair.

Dr. **ALFRED SMITH** showed an interesting Pathological Ovary which he had removed from a patient, aged 25 years, who enjoyed good health up to Christmas, 1899, when her abdomen commenced to become distended. She rapidly emaciated, was extremely weak, and on admission into hospital no diagnosis could be made, the distension from the *free ascites was so great* On exploration the *omentum* was found to be quite solid, mobile, confined to the upper abdomen, and in appearance like boiled sago grains; it bled easily. The left ovary was normal. The right ovary was of normal size and consistency; it showed in the fresh state numerous small whitish warty elevations in appearance not unlike grains of boiled sago, identical in appearance with the omentum. Microscopic examination showed that these growths consisted of a delicate stroma, containing in its meshes, in a somewhat alveolar arrangement, groups of large globular degenerate looking cells. The nucleus was eccentric and flattened against the cell margin; in many cases it was broken up and absent, whilst the protoplasm, containing many oil droplets, yielded the typical fatty and mucoid reactions. In parts the growth seemed to be converted into true fat. It sprang altogether from the surface of the ovary and did not infiltrate the subjacent tissues. The section of omentum gave the same characteristics. The fluid in the abdomen was light brown or straw-coloured; it contained no blood and poured out quite easily.

Dr R D **PUREFOY** read some cases from his Clinical Report of the Rotunda Lying-in Hospital for 1898-1899—Dr. A. **SMITH** criticised the absence of the date of entry into and departure from hospital of patients. He pointed out that a new expression ("mixed hæmorrhage") had been introduced as a form of accidental hæmorrhage and he considered the use of this term a mistake, as it was quite unnecessary. It was curious that several of these accidental hæmorrhages occurred rather early in pregnancy. He pointed out cases occurring in the eighth, seventh, and sixth months, and he thought it was not proved satisfactorily that these were really cases of accidental hæmorrhage. There was a case of locking of twins recorded but on reading the account he could not agree that they were looked at all in the ordinary sense. On page 12 of the report the serre-nœud was stated to have been employed in a Porro's operation. He himself would not think of using a serre-nœud at all, and he did not see why they should go back to the old Porro's operation, when they had modern methods of doing it. He congratulated Dr. Purefoy on the mortality, which was very low. The hospital still maintained its high position among similar institutions.—Dr. W. J. SMYLY agreed with Dr. Smith in deprecating the use of the expression "mixed accidental hæmorrhage." When he was master of the Rotunda he followed the rule that the indications for the forceps should be danger to the mother or danger to the child, and the result was that he had only 20 forceps cases in the house. If this rule was still followed he asked why there were 40 forceps cases one year and only 20 another year? All through the report he found little imperfections which seemed to show that it had been carelessly put together.—Dr. F. W. KIDD said that they need not pay attention to the clerical errors appearing in the report. It was stated in reference to a case of rupture of the uterus that strips of iodoform gauze ten yards long were passed through the rent in the uterus into the abdominal cavity. This seemed to him an extraordinary length, but perhaps it was a clerical error.—Dr. H. JELLETT, speaking of the treatment of abortions, remarked that the number of cases in the house that were curetted was nearly 50 per cent. Though he could not say that the curetting had led to any bad results he thought they would do harm if they sent out men with the idea that 50 per cent. of abortions required curetting. The same idea had occurred to him as to others regarding the term "mixed hæmorrhage," but certain German writers divided accidental hæmorrhage into concealed, external, and mixed, the last meaning cases in which there was sufficient of both concealed and of external hæmorrhage.—The PRESIDENT said that though the mortality and morbidity results were very good he agreed that most of the cases had been reported in such a way as to leave the important points out. He commended the term "mixed hæmorrhage."—Dr. PUREFOY said that owing to the advanced hour of the evening he would like to defer his reply until the next meeting of the section.

HARVEIAN SOCIETY OF LONDON.—At a meeting of this society, held on March 1st, Dr. W. H. Lamb, the President, being in the chair, Dr. Risien Russell made a communication on the Clinical Evidence upon which they Relied for the Localisation of Cerebellar Disease, illustrating his subject by lantern slides. While dealing with the question from a clinical standpoint frequent reference was made to the evidence derived from experimental physiology, and Dr. Russell showed how this was to be utilised in clinical work. In referring to the attitude which characterises a unilateral lesion of the cerebellum (inclination of the head to the affected side so that the ear and shoulder were approximated, and rotation so that the chin pointed to the opposite side) he said that this sign could not be too implicitly relied on in clinical investigations and quoted a case in which a tumour was situated in the opposite lateral lobe of the cerebellum to that indicated by the patient's attitude. Moreover, he had met with cases of cerebral tumour in which the same sign had been present in one of which the growth was situated too far forward to allow of the possibility of direct pressure on the superior peduncle of the cerebellum. Rotation was so rarely met with clinically and the direction of reeling was so inconstant that these phenomena were of little value in localisation, but ataxy of the limbs was commonly more marked on the affected side in unilateral lesions of the cerebellum. Motor paresis was sometimes met with in the limbs on the same side as the affections of the cerebellum and was an indication of cerebellar insufficiency, for such theories as had been advanced to account for it by pressure on the pyramidal fibres could not account for the fact that the phenomenon had resulted from softening of the cerebellum consequent on vascular occlusion. Convulsions did not belong to the symptomatology of cerebellar lesions, except as consequences of secondary disturbance of other parts of the central nervous system, unless Dr. Hughlings Jackson's view were accepted that peculiar tetanic-like seizures which occurred in certain cases of tumour of the middle lobe were of cerebellar origin. Rigidity followed experimental ablation, but when present as a result of disease of the cerebellum it usually indicated secondary interference with the pons, for with the cerebellum alone affected there was more likely to be hypotonia of the muscles. The state of the knee-jerks afforded little aid in localisation, for while there might be increased activity on the affected side, as after experimental ablation, there might, on the other hand, be diminution on this side or there might be great variability, or both might be abolished. Valuable information as to the side affected was derived from evidence of implication of the fifth, the seventh, and the eighth cranial nerves, and, in a few cases, of the twelfth; but even this evidence could not be relied upon as infallible, for in some instances one or other of these nerves might suffer on the opposite side instead of on the side of the cerebellar lesion.—Dr. Leonard Guthrie cited cases illustrating the difficulty in localising cerebellar lesions and even in deciding whether they existed at all. A boy, aged five and a half years, had typical "cerebellar" gait, loss of knee jerks, ataxy, and "intention" tremors of the upper extremities, left-sided facial paralysis, headache, and increasing drowsiness and languor for nearly three months. He then made a rapid recovery and three years later remained in perfect health. Here symptoms of cerebellar disease were probably due to polyneuritis. Another boy, aged seven years, had cerebellar gait leading to astasia, weakness and ataxy of the right arm, loss of the left knee-jerk and exaggeration of the right, double optic neuritis, vomiting, and frequent headache referred to the left frontal region. The symptoms pointed to right-sided cerebellar lesion, but a cyst of the middle lobe of the cerebellum was discovered. This case showed that the "crossed cerebellar" headache was not so valuable a localising sign as it had been held to be. A lad, aged 18 years, who was now under observation, had "intention tremors," ataxy, and weakness of the right arm, slight spasticity of the right leg, with exaggerated knee-jerk and ankle-clonus but normal plantar reflex, shambling awkward gait, double optic neuritis, but neither headache nor vomiting. The symptoms, apart from the optic neuritis, resembled those produced by destruction of the right cerebellar hemisphere, yet they were not conclusive evidence of such a lesion. Finally, Dr. Guthrie mentioned a case in which symptoms pointing strongly to tumour of the right cerebellum proved to be due to tumour of the corpora quadrigemina.—Dr. H. A. Caley remarked on the clinical importance in relation to localisation and spoke of the association in some cases of unilateral paresis with a lesion of the cerebellar hemisphere on the same side. To overlook this point might lead to serious error in differentiating between cerebral and cerebellar lesions.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—An ordinary meeting of this society was held in the Medical Institution, Hope street, Liverpool, on Feb. 15th, the President, Dr J. B. Hellier, being in the chair.—Dr. H Briggs (Liverpool) showed: 1. A Fibro-myoma almost completely calcified removed from a patient, aged 60 years, by Baer's operation. The tumour weighed five and a quarter pounds. The patient made a good recovery. 2. A Calcified Fibro myoma weighing five and a half pounds enucleated from the parametric cellular tissue of a woman, aged 52 years. The patient died on the eighth day from exhaustion. In both cases ascites was present.—Dr. Lloyd Roberts (Manchester) showed a Calcified Fibro myoma of the size of a child's head removed post mortem from a woman, aged 70 years.—Dr T. B. Grimsdale (Liverpool) exhibited a Uterus with Multiple Fibro myomata removed per vaginam by morcellation.—Dr. J. E. Gemmell (Liverpool) showed a Fibro myoma removed by enucleation from a uterus three months pregnant. The pregnancy was not interrupted.—Mr. J. E. Burton (Liverpool) exhibited a Pedunculated Fibro-myoma removed by abdominal section.—Dr. A. Donald (Manchester) read Notes of a Case of Ruptured Extra uterine Pregnancy and showed the specimen. The patient, aged 30 years, had been married four and a half years and had had no previous pregnancy. The menstrual periods were regular until October, 1899, but in that month the period was delayed four days. Uterine hæmorrhage then came on and lasted until the date of operation (16 weeks). In December the patient had sickness and nausea and was seized with pain in the right iliac region. Early in January, 1900, the sickness was very severe. The abdomen was distended and tender, and an obscure swelling was felt bimanually in the right iliac region. The diagnosis was tubal pregnancy with rupture into the right broad ligament.

Palliative treatment was recommended as it seemed probable that the embryo had succumbed. The conditions improved somewhat—although the sickness was at times troublesome—until Feb. 3rd, 1900, when the patient had severe abdominal pain and marked increase of sickness and exhaustion. On Feb. 6th abdominal section was performed. The abdomen contained large clots and much fluid blood. A four months' fœtus and placenta were found lying loosely amidst coils of intestine. No sac and no amniotic fluid were seen. The pelvic organs were not felt, as they were completely shut off by adhesions. The abdomen was cleansed with gauze sponges, but no attempt was made to remove clots adherent to the intestines. A large quantity of iodoform gauze was packed into the abdomen. Convalescence after the first 48 hours was uninterrupted. The case was probably one of secondary rupture into the abdomen. Neither the fœtus nor the placenta showed any signs of maceration or degeneration. From a clinical point of view it was interesting that the most prominent symptom throughout was the vomiting and that even after the final rupture pain and exhaustion and symptoms of peritonitis were more marked than the signs of hæmorrhage.—Remarks upon the case were made by Dr. H. Briggs.—Dr. T. B. Grimsdale related a case of Metrorrhagia occurring in a single woman, aged 31 years. The bleeding had been almost continuous for three years. She had been in bed for 18 months and various modes of treatment, including plugging and electrical methods, had been tried without effect. Vaginal examination revealed no cause for the bleeding, the uterus being small and mobile. The uterus was explored and curetted, but three weeks later the bleeding again commenced with little diminution of the amount. The patient was extremely anæmic. Examination of the blood only gave evidence of simple anæmia. Abdominal section was performed and the ovarian arteries were ligatured. The bleeding immediately ceased and since then the patient had had a normal menstrual period lasting five days.—Remarks were made by Dr. Briggs, Dr. Donald, and Professor Sinclair.—Dr. Grimsdale replied.—Dr. Nathan Raw related two cases of Eclampsia treated with success. In the second case the patient appeared to be moribund for some hours after delivery. Two pints of normal saline solution were transfused into a vein. This was followed by immediate improvement and life appeared to be undoubtedly saved by this measure. Dr. Raw also showed a full term Fœtus removed by Cæsarean section after repeated attempts had been made to deliver by forceps. The child was dead, but the scalp and vertex showed extensive subcutaneous hæmorrhage.

MANCHESTER THERAPEUTICAL SOCIETY.—A meeting of this society was held on Feb. 28th, Professor J. Dreschfeld, the President, being in the chair.—Dr. Walker Hall made a communication on Mercuriol in Syphilis, describing Ahman's method of treating syphilis by means of cotton bags which were fastened to the front of the body and charged with mercuriol. The method was the outcome of Professor Welander's views as to the absorption of mercury when applied to the external surface being chiefly due to inhalation of the volatilised mercury. Mercuriol was described as an amalgam of mercury, aluminium, and magnesium, containing 40 per cent. of mercury. It was first prepared by Apoteke Blomqvist. It was stated that in this preparation the globules of mercury were in a condition of much finer division and were therefore more rapidly volatilised. The method were carried out by means of putting five grammes of mercuriol into a cotton bag (Welander's bag), which was fastened round the patient's body. These bags had a twill surface outside and a smooth soft texture inside. For a course of treatment 20 powders of five grammes each were required. For the first five days one powder was put in the bag every evening and afterwards a powder was put in every other day. The advantages claimed for the method were that it was the most elegant mode of administering mercury and that it was effective without producing bad results, such as dermatitis, stomatitis, or gastritis. The only precaution necessary during the treatment was to test the urine at least once a week, should albumin appear the treatment should be stopped for a few days. Dr. Hall showed specimens of mercuriol and of the bags used in the treatment.—Dr. R. B. Wild stated that he was using mercuriol but had not tried it long enough to be sure of the results. He doubted whether any method would cure syphilis in such a short time.—Professor Dixon Mann doubted whether mercuriol was a true amalgam. Globules of metallic mercury could be seen in it by a lens.—The President referred to a recent paper on the method of treatment by Dr. Schuster, who had obtained no good results from it and who had had to return to the use of mercurial ointment.—Dr. R. T. Williamson made some remarks on the Diminution of the Sugar Excretion in Diabetes during Medical Treatment, in which he pointed out how difficult it was to be certain that the diminution of sugar excretion was actually due to medicinal treatment. In mild cases of diabetes many factors might come into play to reduce the sugar excretion and it was necessary to eliminate these before drawing conclusions as to the beneficial action of drugs. Bearing this in mind he was, nevertheless, inclined to believe from experience in three cases that salicylate of soda did sometimes exert a favourable influence. In these three cases of mild diabetes in old people the sugar excretion diminished or disappeared after administration of sodium salicylate, although the patients were allowed to take nitrogenous and fatty foods and as much white bread and milk as they wanted, potatoes and sugar being practically the only foods excluded. Dr. Williamson found it necessary to increase the amount of sodium salicylate to 80 grains or 100 grains per day, and had not found any serious complications arise from these large doses.—Professor D. J. Leech read a paper on Saline Baths. He referred first to the pharmacological effects of the external and internal applications of sodium chloride solutions of various strengths, and then gave an account of some English and continental health resorts where sodium chloride waters were used medicinally, mentioning the various kinds of cases which were said to be benefited by the different baths. Professor Leech pointed out that the bromides and iodides present in some of these waters were in such insignificant amount that they could produce no effect, but calcium chloride in many cases was present in considerable quantity and might account for some of the beneficial results obtained by drinking certain waters.—The discussion on this paper will be taken at the next meeting.

CHELSEA CLINICAL SOCIETY.—An ordinary meeting of this society was held on Feb. 20th, Mr. J. Foster Palmer, the President, being in the chair.—Dr. Ewart gave an account of a case of Relapsing Pernicious Anæmia. The patient, a man, aged 43 years, had had eight attacks in all, from each of which he recovered under appropriate care and under treatment usually by arsenic, but on two occasions by iron. In December, 1899, he became an in-patient of St. George's Hospital and was treated with mercury and iron, together with daily supplies of soup made of mixed vegetables. The result was a great improvement in every respect.—Dr. Ewart also gave details of a case of Vertical Displacement of the Liver and Stomach and discussed the probable mechanism of the affection.—Dr. Vincent Dickinson read a paper on Gynæcological Therapeutics. There has always existed, he said, a school of practitioners whose aim has been to found a rational system of treating disorders of the female genito-urinary systems by vaginal injections and antiphlogistic drugs, their operation procedures being limited to the use of the lancet and a stick of lunar caustic. Recent improvements in surgery and the advent of the "abdominal surgeons" had brought about great changes in this department of practice, but in suitable cases it might be useful to give a more extended trial in the light of modern knowledge to some of those old bulwarks of the "Art of Physic" which without doubt made the reputation of the Sydenhams, the Lettsoms, and the Harfords of the last century. The subject was then reviewed under the following heads:—1 External applications, including caustic, astringent, antiseptic, resolvent, and anodyne. 2 Drugs exhibited internally, special reference being made to the use of cimicifuga in dysmenorrhœa, assafetida in repeated abortion, helenin, pulsatilla, salix nigra, viburnum prunifolium, &c. 3 Douches and baths, including the application of heat and cold. 4. Rest, exercise, and position. The use of the inclined plane, which was known to Hippocrates, was of value in the treatment of enlarged and prolapsed ovaries and in threatened attacks of pelvic peritonitis and irritation of the bladder. A less degree than raising the foot of the bed from 12 to 18 inches would not produce any effects. The effect of position on displacement of the uterus was also discussed. 5. Electricity. The results were best in the hard variety of fibro-myoma of the uterus and relief was often given to hæmorrhage and pain, although no appreciable diminution in the size of the tumour could be ascertained.—A discussion followed in which the President, Dr. A. Symons Eccles, and Dr. C. A. Morris took part.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held at 20, Hanover-square, W., on Feb. 28th, Dr. H. Radcliffe Crocker, the President, being in the chair —The President showed: (1) A man, aged about 50 years, exhibiting the Beneficial Effects of Treatment by a Free Use of the Knife in Rhinophyma; and (2) a case of Urticaria Pigmentosa in a boy, aged 14 years.—Mr. F. Jaffrey (introduced) showed a case of Urticaria Pigmentosa in an infant aged 12 months.—Dr. T. D. Savill showed: (1) A Case for Diagnosis in a man: ? Psoriasis, ? Seborrhœic Dermatitis; and (2) a boy with a Body Eruption of groups of Pruriginous Lichenous-looking Papules.—Dr. P. S. Abraham showed: (1) A man with Acne Varioliformis; and (2) a woman with Alopecia Areata. In the case of acne varioliformis there were similar spots on the backs of both hands.—Dr. Radcliffe Crocker remarked that it might be a case of the "acne lupus" of Tilbury Fox, and it appeared to correspond with his own description of "adenoid acne."—Dr. D. Walsh showed a case of a girl, aged 22 years, with very marked œdematous infiltration of the left hand and wrist, which condition had lasted for many weeks. A few months ago she had a similar attack which lasted several weeks and then cleared up. The right hand had also previously been twice attacked. There was a rheumatic history including heart trouble.—Mr. G. Pernet suggested that it was a case of hysterical œdema and gave references to similar conditions mentioned by Sydenham and Charcot.—Dr. Crocker was not familiar with the condition.—Dr. A. Eddowes showed: (1) A case of Sycosis; (2) a woman with Erythematous Patches on the Face and Neck; (3) two cases of Alopecia; (4) a male patient, aged 50 years, with (? specific, or ? malignant) Ulceration of the Left Cheek and Ear; (5) a man, aged 50 years, with Lichen Planus of seven years' standing and with Eczema Seborrhœicum of two years' standing; and (6) a woman aged 20 years, with Bazin's Disease.—Mr. G. Pernet exhibited a Hair from the Upper Lip from a case of Tinea Nodosa, showing the mycelial tubes closely arranged, side by side, bound together by cement substance, and growing more or less at right angles with the hair shaft. The cement substance formed a continuous covering over a free edge —Mr. Pernet also read a note of a case of Tinea Versicolor of the Face, by Dr. Arthur Powell of Kalain, Cachar, East Bengal. Photographs of the case were shown and the fungus prepared from scrapings was also exhibited under the microscope.—The President, Dr. Rufenacht Walters, Mr. T. J. Hitchins, and others joined in the discussions.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held at the West London Hospital on March 2nd, Mr. L. A. Bidwell, the Vice-President, being in the chair.—Dr. Campbell Pope showed a case of Bradycardia in a child. The girl, aged nine years, had had pleuritic effusion on the left side following whooping-cough two years previously. She had also been run over and had been kicked in the head by a horse. The usual pulse-rate was 33.—Dr Campbell Pope also showed a man who had been operated on by Mr. Marmaduke Sheild for Abscess of the Spleen.—The cases were discussed by Dr. Seymour Taylor, Mr. Rickard Lloyd, and Mr. L. A. Bidwell, and Dr. Campbell Pope briefly replied.—Dr. Seymour Taylor showed a case of Palsy of the Sixth, Seventh, and Eighth Cranial Nerves.—Remarks were made by Dr. S. D. Clippingdale, Mr. G. Pernet, Dr. Campbell Pope, and Mr. R. Lake, and Dr. Seymour Taylor replied.—Dr. Phineas Abraham showed two cases of Skin Disease: (1) a case of Pemphigus, and (2) a case of Dermatographia. The latter was an extremely well-marked instance of a rare affection. Some words which had been written on the skin of the chest in the afternoon were quite distinct at a late hour in the evening and indeed still stood out prominently from the surrounding skin —Mr. L A. Bidwell made some interesting remarks on the condition and Dr. Abraham replied.—Mr. H. J. Paterson showed a case of Psoriasis. There was great difficulty in the diagnosis between simple and syphilitic psoriasis. Although the eruption had the character of a syphilitic rash, and although it had not the appearance and distribution on which they relied in making a diagnosis of simple psoriasis, yet the general opinion was that the case was one of simple psoriasis —Remarks were made by Dr. Phineas Abraham, Mr. G. Pernet, and Dr. T. H Dickson.—Mr. L. A. Bidwell showed two cases of Pyloroplasty.—Dr. A. H. W. Clemow showed a case of Excision of the Pylorus in which the operation had been performed by Mr. C. B. Keetley with excellent result.—Mr. Matthews Duncan, for Dr. F. G. D. Drewitt, showed a case of Aneurysm of the Aorta in a woman aged 41 years.—Mr. Bassano showed a man suffering from great Deformity of the Chest on the left side due to congenital absence of ribs.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held at the Kidderminster Infirmary on March 2nd, Mr. J. Lionel Stretton, the President, being in the chair.—The President read notes of the case of a female infant, aged 19 months, who was brought to him because she made a Double Stream of Urine. On examination two small orifices were discovered, one close to the clitoris and a second about three quarters of an inch behind it; a probe passed in at the anterior orifice struck a director passed in at the posterior orifice. On slitting up the tissue between the two orifices the urethra was discovered immediately under the posterior one; the vestibule had been roofed by the adhesion of the two labia minora and the only escape for the urine was through two small openings. The condition was congenital; no mention of it was found in the ordinary text-books.—The President also showed a multilocular ovarian cyst which he had removed from a woman, aged 53 years. It had evidently ruptured some time before removal as the abdominal cavity contained much fluid and there was a round hole in the cyst wall through which the fluid had escaped. The cyst weighed 8 lb. and 12 pints of fluid were removed. The rupture of the parent cyst had not given rise to any acute symptoms —Dr. B. Addenbrooke read notes of the case of a woman, aged 36 years, who had been confined one month previously, delivery being instrumental. 48 hours after labour she had a maniacal attack which passed off in a few days and she did well for a fortnight, when she complained of a swelling extending from the left inguinal region to the mid pubes. An incision was made, foul-smelling pus was evacuated, and on introducing the finger the pubic bones were found to be bare and separated about one-eighth of an inch. The patient made a good recovery.

ERRATUM.—In the report of the meeting of the Society of Anæsthetists in THE LANCET of Feb 10th, p. 389, the expressions "specific gravity 1017" and "specific gravity 0 817" and 1020" ought to be respectively "specific gravity 0 820."

Reviews and Notices of Books.

Essentials of Modern Treatment of Disease: for the Use of Practitioners. Alphabetically arranged for ready reference By K. M. NADKARNI, Associate Editor *Indian Medico-Chirurgical Review*; formerly Editor *Doctors' Magazine*, Bombay; Fellow of the Incorporated Society of Science, Letters, and Art of London, &c. , Madras: N. K Rao and Co. London: Baillière, Tindall, and Cox. 1898. Price Rs. 4 and Rs. 5.

WE do not think that the aim of this little work can be better stated than has been done in the preface. Its author's object has been to supply the busy practitioner with a pocket compendium of ready reference containing an epitomised account of the various modes of treating each disease recommended by eminent authorities of various countries in order to widen the resources of the practitioner as far as practicable. It contains some 460 pages and consists of two parts which can be obtained bound together in one volume or separately in two, each with interleaves. For facility of reference it could not be well improved. The treatment of 600 diseases is arranged alphabetically and 800 prescriptions gleaned from various sources are also added. It need scarcely be said that in addition to the standard and recognised treatises which have been laid under contribution a voluminous amount of periodical literature devoted to medical science has of necessity had to be consulted and ransacked in the compiler's therapeutical journey in search of well established and useful methods of treatment as well as of those of a more novel and consequently less accredited kind. In a work of this kind everything obviously depends upon the amount of care, judgment, and discrimination exercised in its production. It would have been impossible to have gone through the volume from cover to cover, nor is it necessary. We have followed the plan familiarly adopted by the cheese-taster—that of testing its nature and quality by small samples from within, and judged in this way the work seems to us to have been brought up to date and to be well done. The plan followed is to give the briefest possible description of the disease, the principles on which it should be treated and the therapeutical indications for its treatment, with the remedial agents and formulæ that may be most usefully selected and employed for obtaining the end in view. Books of this kind are not of course intended to teach what should have been acquired elsewhere or to give that kind of scientific and systematic knowledge which the practitioner presumably possesses already, but to afford a ready reference and reminder to such as are busily engaged in the practice of their profession, and this the little handbook on the "Essentials of Modern Treatment of Disease" seems calculated to do.

Microscopic Researches on Glycogen, Part II.: Glycogen of Snails and Slugs in Morphological and Physiological Correspondence with the Lymph System of Vertebrates. By CHARLES CREIGHTON, M.D. Aberd. With Plates. London: Adam and Charles Black. 1899. Pp. 127. Price 7*s.* 6*d.*

IN the first part of this work, published in 1896, Dr. Creighton gave the details of his observations on the characters and functions of glycogen in the embryos of mammals, and showed how he had been led to regard it as the precursor, or the temporary substitute, or the accessory of red blood. In the present part he describes with great precision the distribution of glycogen in the invertebrata, the mode in which, and the period when it is deposited in various examples, and develops at some length the view which he has been led to adopt. The relations between glycogen and the lymphatic and hæmal systems do not at first sight seem obvious. It is startling to find a solid carbohydrate starch or its modification regarded as the blood of vegetables, and to discover further that in Dr. Creighton's opinion glycogen or animal starch is coordinate in value with the blood or lymph of animals, but the reasoning by which he has been led to this conclusion is both ingenious and cogent. There can be no question that starch plays a very important rôle in vegetable life. It is very constantly present when growth and development are about to take place, being sometimes stored up in large quantities in roots and tubers and bulbs, and these stores are exhausted as development and growth proceed. It is not, then, unreasonable to name starch as a fixed instead of a fluid nutriment and to regard it as the equivalent in plants of the blood in animals. The occurrence of a substance in animals resembling starch in composition but differing from it in giving a red reaction with iodine instead of blue has long been known, and Dr Creighton has collected the observations of many chemists and biologists showing how much attention has been paid to this subject and how wide is the distribution of animal starch. It has been found in protozoa, less distinctly in cœlenterata and vermes, very clearly in the chief families of mollusca, and in arthropods. Great interest attaches to the positions occupied by the material. In the higher mollusca, which have been the special object of Dr. Creighton's investigations, it is accumulated around the vessels and is contained in large plasma cells around those of the nerve centres and of the digestive and generative tracts—that is to say, exactly in those parts which are nearest to the sources of supply and those in which the most active processes are taking place. In the arthropods it is also found in the organs of reproduction as well as elsewhere at certain stages of development. Now, the plasma cells in the mollusca mentioned above, with their contained zo-amyline, occupy the position of the vascular sheaths of the vertebrata, and just as the tissues in the vertebrata derive their pabulum from the lymph which circulates in the perivascular sheath so do the tissues of the mollusca draw their nourishment from the carbohydrate stored up in the plasma cells. In the vertebrata the original vascular system of the molluscan series no longer contains a lymph-like fluid, but is filled with red blood. The nitrogen required for the assimilative processes must of course be derived from other sources, as from the plasma of the plasm cells or from some combination with proteid which the glycogen subsequently forms, and in connexion with this it is to be remembered that glycogen is present in large quantity in embryonic structures where it precedes or accompanies the development of blood and in various pathological formations. The treatise is illustrated by many original drawings and is well worthy of study.

La Pratique des Accouchements: Obstétrique Journalière (Midwifery Practice: Everyday Obstetrics.) By Professor HENRI VARNIER. Paris: G. Steinheil. 1900. 8vo. 440 pp. in Two Columns. 387 Illustrations. Price 26 francs.

THE ideal which the author has laid before himself in this book is to produce a work which will enable the student when consulted by a patient who believes herself to be pregnant to recognise the condition, to carry the patient safely through her period of gestation, and to ensure for her a safe and normal delivery of a living child and an uncomplicated puerperal period.

The "Obstétrique Journalière" is divided into four chapters. The first of these is concerned with the Diagnosis and Hygiene of Normal Pregnancy. With the aid of reproductions of all the most important sections of early pregnant uteri the author points out that the diagnosis of pregnancy in the first few months depends upon the recognition by physical examination of the typical tumour formed by the developing uterus. As he is a follower of Professor Pinard it is not surprising to find that the study of the uterus during the second half of pregnancy by abdominal palpation is discussed in great detail. Not only are the methods of recognising the normal position of the fœtus fully explained, but in cases where any abnormality of presentation is met with the method of correcting it by external manipulation is clearly laid down. This is one of the best chapters of the book and is illustrated by a large number of photographs and drawings from nature. The concluding section of the first part is devoted to an account of the best methods of performing the important duties imposed upon a medical man who is responsible for the care of the health of a pregnant woman. He must take means to safeguard her from all conditions likely to produce a premature confinement, and he must carefully regulate the various functions of the body, especially those of assimilation and excretion, so as to ensure for the infant a rapid and safe birth and for the mother a normal confinement and puerperium.

The second chapter treats of the diagnosis, prognosis, and conduct of labour, and also contains an analytical and clinical study of its course. That the long-debated question as to the condition of the cervical canal at the commencement of labour may be finally considered as decided is amply proved by the author's researches and his figures. The stage of dilatation of the cervix and the part played by the bag of membranes is admirably described and illustrated. The author's method of preserving the perineum is shown by a series of photographs.

He aims at preventing the birth of the forehead and the occurrence of extension of the head until the parietal eminences have emerged from the vulva and the neck has become well engaged under the symphysis pubis In his analytical study of the course of labour Professor Varnier enables us to follow (very fully), with the aid of many excellent illustrations, the various changes that occur in the genital canal, the uterus, and the child during the progress of the latter through the pelvis. Under the Prognosis and Conduct of Labour its duration, its special characters in old primiparæ, the effect of occipito-posterior presentations and of multiple gestation are all considered. Lastly, the indications for the applications of forceps and the special dangers of their use are discussed.

The Delivery of the Placenta and Membranes is studied, partly anatomically and partly clinically, in the third chapter. The researches of Schroeder, of Barbour, and of Pinard, in conjunction with the author, are all quoted. The reader is given the choice of three methods of delivering the placenta—traction upon the cord, Credé's method of expression, or the combined method recommended by Professor Pinard of traction and expression.

In the last chapter the author describes the progress of a normal puerperium and the changes that occur in the genital canal and the uterus. The description of the involution of the uterus is particularly full and is illustrated by numerous original drawings and photographs. A most interesting historical account is given of puerperal fever, and the great debt that we owe to the labours of Semmelweiss, Simpson, Pasteur, and Lister is duly acknowledged.

The necessary details of antisepsis and asepsis in midwifery practice are treated with great fulness and a most complete account is given of the various organisms met with in the different varieties of septic infection and septic intoxication.

The printing and illustrations are worthy of the highest praise and the author is to be congratulated upon the production of a most interesting book embodying the results of a large amount of original work of great value. An intelligent study of this volume should go far towards equipping the student with a complete knowledge of the course of normal labour and enabling him to become the perfect accoucheur of Dionis, who holds, as Professor Varnier points out, that such a man should be a "man of perfect honesty and skill, simple, unaffected, and full of sympathy for the sufferings of women in childbed."

Spencer's Disease. Dermatitis Multiformis Exfoliativa. By WALTER SPENCER, M D Brux. London: Pewtress and Co.

THE author of this pamphlet of 16 pages anticipates the gratitude of posterity and christens what he considers to be a new disease after his own name. The disease broke out in a lying-in hospital in Sydney to which the author is physician, and between Oct. 1st, 1898, and March 31st, 1899, out of 48 children born 25 were attacked and five died. The elementary lesion varied, showing "erythema, macule, papule, vesicle, pustule, or bulla as the initial sign." It was an infectious dermatitis of sudden onset without premonitory symptoms, showing special affinity for infants under three weeks old but avoiding adults, usually unattended with any constitutional symptoms, and the polymorphic eruption underwent a rapid evolution until it became lost in exfoliation more or less extensive In cachectic subjects it proved rapidly fatal. The author, after comparing the symptoms with those of Ritter's disease, pemphigus neonatorum, and other somewhat similar affections, came to the conclusion that it was a disease *sui generis*. As far as we can judge from the author's description the condition was probably due, like pemphigus neonatorum, to staphylococcus aureus infection and the sanitary arrangements of the hospital should be carefully investigated.

A Manual of Diseases of the Nose and Throat. By CORNELIUS GODFREY COAKLEY, A.M., M D. London: Henry Kimpton. 1900

THIS is a handy and well-printed volume of 536 pages. It contains a full index, 92 engravings, and two coloured plates Generally speaking the engravings and plates are well executed. Special attention is devoted to the methods of examination and diagnosis. Although both in diagnosis and also in treatment many considerations and methods are omitted, the author aims at describing those which his experience at the New York hospitals leads him to believe are most trustworthy and useful to the student and practitioner The book is not quite free from faults so often noticed in "special" treatises on the throat and nose. For instance, to make seven varieties of hypertrophic rhinitis seems hardly needful. The chapter on Laryngeal Nerve Affections is distinctly good and clear. Professor Keen has added a short chapter containing his methods of performance of the more extensive laryngeal operations. A feature of the book is an appendix of excellent formulæ which are also scattered through the book. Altogether this work may be recommended to students and practitioners as a trustworthy guide for diagnosis and treatment of the maladies with which it deals.

LIBRARY TABLE.

Natural and Artificial Methods of Ventilation. London: Robert Boyle and Son, Limited. 1899. Pp. 66 —The contents of this little anonymous book appear to have been collected to form a diatribe against all mechanical or artificial means of ventilation. Of course, we have yet to learn how to ensure efficient ventilation that shall be conducive at the same time to comfort and to health. There are arguments in favour of so-called natural ventilation and there are arguments in favour of so-called artificial ventilation. Which is best adapted for the purpose depends mainly on the circumstances of environment. After all, ventilation implies essentially the removal of contaminated air and it does not matter much whether this removal be effected by the vagaries of atmospheric movements or by mechanical contrivances. That efficient ventilation is essential to health no one disputes and everyone will welcome the system which best fulfils this end This little contribution is very instructive and those who would be familiar with the *pros* and *cons* of the various methods of ventilation will find it a convenient source of reference.

CORNELIA HOSPITAL, POOLE.—At the annual meeting of the friends of this institution, held on Feb 28th, it was stated that there was a deficiency of £700 during the past year, and that Lady Wimborne had paid it off.

CARDIFF INFIRMARY.—The annual meeting of governors and others interested in this institution was held on Feb 28th under the presidency of General Lee. The annual report stated that during 1899 there had been 1700 in-patients admitted. The out-patients numbered 13,556, an increase of 513 as compared with the preceding year The financial statement showed that the ordinary income amounted to £6988, an increase of £98 as compared with 1898 Legacies and donations amounted to £2600 and the subscriptions of working men had increased by £300. The total expenditure was £9050, an increase of £520 as compared with the previous year. The chairman stated that the adverse balance of the infirmary was now about £8000

THE LANCET.

LONDON: SATURDAY, MARCH 10, 1900.

THE analysis which we have given of that portion of the report of the Indian Plague Commission dealing with the anti-plague inoculations will have shown that it is a very able and painstaking criticism of the HAFFKINE system. Nothing of importance has been omitted in the survey by the Commission, and though their views on the bacteriological aspects of the subject are somewhat theoretical in their character, as distinguished from the results obtained by the practical application of the prophylactic, yet the report forms, on the whole, a valuable commentary on the inoculations and will strengthen the basis on which they are founded. We search in vain, however, for a due and sympathetic appreciation of the great work performed by Mr. HAFFKINE and by the medical men and civil officers who have assisted him. In its absence it is particularly gratifying to notice that Lord CURZON, in the resolution of the Government of India on the Commission's report, has not forgotten this aspect of the question and has paid a high tribute to Mr. HAFFKINE.

It is evident from a perusal of the report that the Commission are not influenced or restrained by any special regard for either the difficulties or conditions under which the work has been carried on in India. The highest scientific standards have been set up and compared with existing arrangements. As might be expected, the comparison is much to the disadvantage of the latter, in which it is shown that important defects obtain in the use of cultures of different ages and in the methods of decanting, bottling, preserving, standardising, and fixing the dose of the vaccine. Fortunately, none of these can be shown to have had any injurious effect on the inoculated, though it is probable that they have placed the prophylactic under unfavourable conditions for attaining the best results. The remedy for these defects is only discussed in a general way, but there can be no doubt that it consists in providing in the laboratory more scientific workers and more plant and making adequate arrangements for manufacture of the vaccine on a large scale. With a more uniform period allowed for the ripening of each culture and the selection of flasks which give a uniform growth there would be no need to vary the dose according to the opacity of cultures, and there would be no difficulty in standardising the vaccine by ascertaining the febrile reaction produced by certain samples. The methods in use and their defects were evidently forced on the laboratory by having to meet a large demand with an insufficient organisation, and now that the Government of India have accepted this portion of the Commission's report we trust that suitable arrangements will be made, if they have not already been carried out, to meet the requirements.

Of even greater importance than the criticism on the methods adopted are the views expressed by the Commission on the composition of the prophylactic fluid and the relative value of its constituents. They are of opinion that the efficacy of the vaccine lies wholly in the bacterial sediment and not in the supernatant fluid. Considering how much this means if true we are astonished to find that the reasons are mainly hypothetical, for the small amount of the evidence and the experiments brought forward cannot be taken seriously to affect the question, while, as a matter of fact, the conclusions based on the experiments mentioned have been discounted to a certain extent by later ones. The arguments against Mr. HAFFKINE's views are academical in their nature until it can be shown by numerous experiments on man that the supernatant fluid is useless in plague inoculations. This is tantamount to beginning the observations on man over again and comparing the prophylactic effect of the bacteria and of the supernatant fluid separately. This has not been suggested by the Commission. In the meantime it is to be noted that not only the plague attacks but also the case mortality in plague are reduced by the present vaccine, the composition of which is based on the experience gained by Mr. HAFFKINE in his observation on cholera inoculations, and by the fact then discovered by him that the bacilli alone did not affect the case mortality.

Nor do we think the Commission have been more fortunate in attacking Mr. HAFFKINE's method of statistical expression and adopting another which is obtained by subtracting percentages. The latter is not only an unusual method, but it is also misleading. To work out the percentage of deaths and attacks among the inoculated and non-inoculated and then subtract the percentages from one another is an erroneous method of arriving at the relationship between the two. We must regard the relationship existing between two quantities as expressed, not by the differences between them which indicates how much larger the one is than the other, but by how many times the one is contained in the other. To illustrate this let us suppose that typhus fever has a mortality equal to 15 per cent. of the persons attacked and measles has a mortality equal to 5 per cent. of the attacks. We cannot express the relation of these by simply subtracting one from another and stating the difference between the percentages as 10 per cent. The actual relation consists in the ratio between the two. Thus typhus fever is three times as fatal as measles. The fatality of the first disease exceeds that of the last by 200 per cent. It is obvious from this illustration that the Commission have been led astray by their own statistics, and we are not surprised to find that they are unable to give an arithmetical value to the results secured by the inoculations. The subject, however, is treated at greater length on p. 724. In this connexion it is only fair to say that in their synoptical tables the ordinary ratios are given. Notwithstanding this defect in the report there can be no doubt as to the thoroughness with which the investigation has been entered into and the care which has been taken before coming to conclusions which are highly satisfactory as regards the merits of the inoculations. From their study of the nature and effect of the anti-plague prophylactic the Commissioners sensibly conclude that the inoculation quickly diminishes the incidence of plague attacks and deaths in the inoculated population, that the protection continues for some weeks, possibly for a number of months, and that under the safeguards and conditions of accurate standardisation and sterilisation of the vaccines and other simple precautions the inoculations should be encouraged whereever possible, and in particular among disinfecting staffs and the attendants of plague hospitals.

◆

THERE are several papers of much interest at the present time, seeing that our thoughts are now focussed on what is going on in South Africa, in the seventeenth volume of the Transactions of the American Surgical Association of 1899 just published. The articles to which we may specially refer those interested in military surgery—as who is not just now with the excellent surgical and other work which is being done by officers of the Royal Army Medical Corps and with the admirable contributions from the theatre of war by Sir WILLIAM MACCORMAC to THE LANCET fresh in their minds—are those on the "First-aid Package in Military Surgery," by N. SENN, M.D.; "Observations upon the Organisation and Equipment of Military Field Hospitals in the Volunteer Army," by GEORGE RYERSON FOWLER, M.D.; and one on "The Effects of Modern Small arm Projectiles, as shown by the Wounded of the Fifth Army Corps during the Campaign resulting in the Capture of Santiago de Cuba," by CHARLES B. NANCREDE, M.D., together with a report of the discussion on the surgery of the Spanish-American war consequent on the reading of these papers.

We cannot on the present occasion deal with the many interesting and important matters contained in the volume of the Transactions of the American Surgical Association but must content ourselves with a brief reference to a few points in the first-named paper. Dr. SENN of Chicago says that it is fortunate for the armed forces of the world but unfortunate for military surgery that no great wars have occurred since antiseptic and aseptic surgery came into general use. This void, we may remark, is being filled in with the results of the recent experience of the Americans and by those of the much wider and more recent experience now being acquired in the campaign in South Africa, which, we may well hope and believe, will add much to our knowledge that will prove of benefit to humanity in general and to the practical improvement of military surgery in particular. During the time that the Franco-Prussian war was being fought LISTER was quietly at work framing the great principles which have altogether re cast the work of the surgeon. Antiseptic and aseptic surgery have not hitherto had a full and fair trial on an extensive scale on the battle-field. Without following Dr. SENN through his brief historical survey of the progress of Listerism and its adaptation to battle-field surgery we may say that he correctly states that the first tentative efforts to practise asepsis in military surgery were made by REYHER and VON BERGMANN in the Russo-Turkish war. Two things were brought out clearly during that war—viz, the value of a first aid antiseptic occlusive dressing in the prevention of wound-infection and the importance of immediate mobilisation of gunshot fractures—the latter being sometimes a very difficult thing to accomplish, we may parenthetically remark, under all the exigencies of battle. REYHER and VON BERGMANN did most excellent service on that occasion in condemning the too common practice of searching for and extracting bullets on the battle-field and in hospitals. It soon came to be recognised that the first great division that has to be made of gunshot wounds, as regards their favourable progress or otherwise, is into the befingered and unbefingered. Although we cannot, unfortunately, in practice trust to such a protective agency wen evertheless carry in our own persons an aseptic material in the blood which is effused, dries up, and seals our wounds if only it could be always kept aseptic and unmixed with any "baser matter" of pathogenic germ origin. We are a long way yet from having realised perfect asepsis on the battle-field and Dr. SENN is obviously right in saying that better results will be obtained by the use of dressing material impregnated with an antiseptic substance than by one composed of simply sterile material.

The value of antiseptic and aseptic precautions in military practice was afterwards demonstrated on a limited scale in Bulgaria, Servia, Chili, Greece, Turkey, Japan, and in Africa and in the late Spanish-American war. In India during the Afghan campaigns and in the late tribal wars on the North-Western frontiers antiseptic precautions and practice were generally followed, and in our Egyptian war of 1882, with its small engagements ending with the battle of Tel-el-Kebir, it was shown that no case of infective wound disease occurred among the wounded, nor did any soldier lose his sight out of the large number of cases of ophthalmia that occurred in the British army serving in Egypt—results attributable to the wide use of antiseptic agents and dressings. Dr. SENN describes the first-aid antiseptic dressings used by different armies, including that of America, and tells us that during the Spanish-American war the Surgeon General issued 270,000 first-aid packages to the troops in Cuba and Porto Rico and the soldiers in home camps. A dry dressing is the best means of preventing wound infection, and, as Dr. SENN points out, nothing should interfere with the conversion of the wound secretion and dressing employed into a dry crust which hermetically seals the wound.

Mr. TREVES has told us, as the result of his experience in South Africa, that the field dressing carried by every British soldier answers its purpose admirably and that Tommy Atkins "has a great regard for it and takes every care he has it on him" All the smaller wounds can be dressed by this means at once and no further dressings are commonly required. The first field dressing now in use in the British army is an adaptation of that employed in the French service. It forms a component part of the soldier's kit on active service so as to be available at all times and in all places as a first dressing for wounds, and when he goes into action it is placed in the pocket on the right side of the tunic. The antiseptic agent used is corrosive sublimate, 1 in 1000, and directions for use of the first dressing are printed both on the outside and the inside covers. A detailed description of this first field dressing, together with some very clear and excellent remarks and directions regarding the objects sought to be obtained and the precautions and methods to be followed in the use of antiseptics generally in wounds and operations, are given in the official manual issued for the men of the Royal Army Medical Corps.

Dr. SENN lays down the requirements which a first-aid package for use in the field must meet, and at the end of his paper he emphasises his conclusions. He declares that first-aid packages are indispensable on the battle field in modern warfare, and in this all who joined in the discussion seemed to be in accord with him; that the dressings should be sufficiently compact and light to be conveniently carried by the soldier and in such a way as to be conformable to military regulations; that the Esmarch triangular bandage, although of great value in the school of instruction, is in a first-aid package inferior to the gauze bandage; that the first-aid dressing must be applied as soon as possible after the receipt of the injury; that the dressing must be dry and should be kept so, and that it should not be disturbed unnecessarily, but any defects should be corrected at the first dressing station. He considers that the first aid dressing, if employed behind the firing line, should be applied by ripping up the clothing over the injured part without removing it. The dressing is to be fastened to the skin with strips of rubber adhesive plaster, the bandage being applied over and not under the clothing.

◆

THE friends of sheer quackery, as well as those persons who in a desire to be open-minded favour the claims of irregular medicine, will point with triumph to the fact that the General Medical Council failed to get a judgment against Mr. ALABONE in the North London Police-court "for wilfully and falsely pretending to be a doctor of medicine, and wilfully and falsely using titles and descriptions implying that he was recognised by law as a practitioner in medicine." It is not in mortals to command success. They can only deserve it. And it may be that the General Medical Council, whose legal procedures have met with considerable criticism, in this case deserved success without attaining it. It may be, however, that though their case was a good one their presentation of it was not.

We withhold a final opinion on this point; but meantime we can explain why, with no prepossession in favour of Mr. ALABONE, the magistrate should have decided as he did. Mr. S. G. LUSHINGTON, the counsel for the prosecution, pointed out that the defendant described himself as EDWIN W. ALABONE, M.D. Bellevue College, M.D. Phil., U.S.A., D.Sc., F.R.M.S., Ex-M.R.C.S. Eng., and added that the degrees of the Bellevue College, New York, and the Jefferson Medical School, Philadelphia, were registrable in this country, and that the defendant had adopted a style which might lead the public to believe him to be a registered medical man. (The titles in question are no longer registrable, but that is a detail[1]). Mr. ALABONE'S counsel, Mr. SCHULTESS YOUNG, naturally made a strong point of Mr. ALABONE'S candour in stating the American source and origin of the degrees on the possession of which he based the use of his titles. Mr. YOUNG said that since the Royal College of Surgeons of England removed Mr. ALABONE from its list of members he had been careful to state the American origin of all his degrees "so that no one could be deceived." Mr. YOUNG took the ground in defending his client that it could not be said that he was wilfully and falsely representing anything when he only represented that which was true. This formed a powerful appeal to the magistrate, and we do not wonder that in the absence of more explicit evidence of the source of Mr. ALABONE'S American degrees the summons was dismissed. The magistrate held, and we think rightly, that because the defendant said that he was an M.D. of Bellevue College and an M.D. of Philadelphia, he must not be assumed to have implied that he was an M.D. of the Bellevue College of New York and of the Jefferson Medical School, Philadelphia, both of which degrees at one time entitled their holders to registration in England. But would the magistrate have taken the same favourable view if the nature of the two institutions whence Mr ALABONE derived his degrees had been brought to his notice by the General Medical Council? It may be said that the admitted facts concerning the way in which Mr. ALABONE'S American degrees were obtained ought to have given sufficient information to anybody on the subject, but we do not think that the magistrate understood what kind of distinctions Mr. ALABONE was candidly laying claim to. The only Bellevue College in the United States, not the Bellevue College of New York, appears to be the Bellevue Medical College of Boston. It is thus described in the list of medical colleges issued by the Illinois State Board of Health:—

> "Bellevue Medical College of Massachusetts, Boston, Mass. Organised in 1880 Fraudulent. Exposed by the Illinois State Board of Health in 1882"

The same excellent publication dealing with medical education in the United States and Canada speaks as follows of the Philadelphia University:—

> "Philadelphia University of Medicine and Surgery (Eclectic), Philadelphia, Pa. Incorporated in 1865. Fraudulent. Extinct in 1880."

There does not seem to be any other Philadelphia University. Now these are not institutions which could give or could ever have given reputable diplomas, diplomas which a man ought to care to have, or which an English court, fully informed, would be likely to regard as other than bogus. But apparently the prosecution was not ready with this full information. The United States is a large place and in the absence of any such evidence it is intelligible that Mr. PAUL TAYLOR should have concluded that the degrees possessed by the defendant were proper *bonâ fide* medical degrees, upon which it followed that he must consider the prosecution instigated by the General Medical Council a vexatious one. It was not a vexatious prosecution, but it does not appear to have been a well conducted one.

◆

THE President of the Local Government Board received at the House of Commons on March 7th a deputation representing various hospitals and infirmaries throughout Great Britain. The object of the deputation was to ask that these institutions should be exempted from local rates. Everyone knows the stereotyped programme for a deputation to a public Minister. The deputation is introduced and proceeds to lay the matter nearest its heart before the Minister. That gentleman replies in the regular official form to the effect that the objects of the deputation are worthy of the highest praise, but that, though these objects are of the deepest interest to himself personally, he is unable to give any other answer than "the subject will be carefully considered," or "a Royal Commission is sitting," or "a Committee to inquire will, I hope, be appointed."

---

[1] These degrees are registrable if obtained prior to June 25th, 1886, as additional titles by practitioners previously registered. (See Medical Register, Table I)

The deputation of Wednesday last followed the usual type. Some of the most influential and hard-working of those interested in hospital work attended, and stated to Mr. CHAPLIN through the medium of a memorial that the institutions in which they were interested were almost entirely carried on by voluntary efforts and that the services rendered were practically given without cost to, or payment by, the public. The institutions relieved the poor-rates to an incalculable extent and yet had to pay towards these rates. The annual amount of rates payable on hospitals and infirmaries in Great Britain was, according to the memorial, about £50,000, of which sum £21,801 were raised in the metropolis of London. Until the year 1865 hospitals were not considered to be rateable, and Parliament had from time to time exempted churches and chapels, buildings occupied by societies for the promotion of science, free public libraries, and Sunday and voluntary elementary schools, from the payment of rates. In Birmingham and Halifax hospitals paid no municipal rates and in Ireland all hospitals and charitable institutions were exempted from paying both poor-rate and county cess. Mr. CHARLES BIRT, who spoke as the representative of the London Central Hospital Fund, added that if London hospitals were exempt from the payment of rates, provision could be made for 4000 more in-patients than at present—a statement that should have great weight at the present time when so many beds in our largest hospitals are closed for want of means. Mr. CHAPLIN, in reply, said that of course everyone must sympathise with the object which the deputation had in view—namely, that the voluntary hospitals should be able to extend their operations even more widely than at present. It was true that there were certain institutions which did not pay rates, and also true that hospitals did not pay rates before 1865. But he was not quite sure that hospitals stood upon the same footing as the institutions which were exempt. It would not follow, for instance, that the relief in all cases would be wholly to the rates of the district in which the hospital was situated. Patients came to some hospitals from all parts of the country and therefore the ratepayers in one particular district would be bearing additional burdens, and not only those of their own people but those of patients who came from a distance and ought to be supported by outside districts. If they were to exempt hospitals where were they to stop? Another point was that the whole matter of local taxation was being considered by a Royal Commission. They must not think, however, that he was the least indifferent to the subject. He would very carefully consider the question and would lay it before his colleagues at the earliest opportunity.

We do not suppose that the deputation expected any other answers than one or more of those which we have indicated as being, and being of necessity, the regular official answers, but Mr. CHAPLIN'S words of reply are by no means convincing to those who advocate the relief that is being prayed for. If only a local institution should be exempt from rates why is it that the London Library, the Royal Institution, and Spurgeon's Tabernacle are exempt? The London Hospital is specially exempted from the payment of rates by a local Improvement Act, so that Mr. CHAPLIN'S doubt as to where things would stop may be answered by a reference to the case of that charity. The rating of the London hospitals produces a sum under £22,000 per annum. Exemption from this tax would mean a great deal to the hospitals in question and would hardly be felt as an addition to the enormous sums now raised by the local rating authorities. Exemption would of course hit some parishes harder than others. Chelsea, for instance, has within a stone's throw of one another two hospitals, and part of a third —namely, the Cancer Hospital, the Chelsea Hospital for Women, and part of the Brompton Hospital for Consumption. But we do not suppose that the loss to this parish of the rates paid by these charities would be so very serious that the case of Chelsea ought to be used as an unanswerable argument against remission of the rates, and in most other parishes exemption would scarcely be felt at all. The deputation, in our opinion, made out a very good case for exemption, and we earnestly hope that the matter will not be allowed to drop, but will again and again be pressed upon the notice of those in power.

Annotations.

"Ne quid nimis."

THE QUEEN'S VISIT TO IRELAND.

WE have learned with admiration of the Queen's expressed intention to visit Ireland next month. Her Majesty's motive is easy to read and does both her heart and her judgment infinite credit. She desires to recognise in the most public manner the remarkable part played in the South African war by her Irish soldiers. That this is the interpretation to be put upon her courageous departure is proved by the following special Army Order, which was issued on Wednesday almost simultaneously with the publication of the news of her impending stay in Dublin:—

> *Gallantry of Irish Regiments in South Africa—Distinction to be worn on St Patrick's Day.*
>
> Her Majesty the Queen is pleased to order that in future upon St. Patrick's Day all ranks in Her Majesty's Irish regiments shall wear, as a distinction, a sprig of shamrock in their headdress to commemorate the gallantry of her Irish soldiers during the recent battles in South Africa.

Her Majesty by this Order, as well as by her desire to sojourn among her Irish people, pays particular and delicate attention to the national susceptibilities of a proud race, who have had in the past distinctly just causes of complaint against the Crown, and many of whom consider that these causes are still in existence. Her subjects in every part of her realms will see with pleasure in the visit to Dublin more evidence of the Queen's motherly tact—another proof of her promptitude to respond in the fittest and fullest manner to her generous instincts. We may feel sure that in Ireland men of every rank, class, and religion alike will make their Queen royally welcome, for they all share with her her admiration of the Irish soldier The courage and devotion of Her Majesty to the best interests of her subjects is displayed in a marked manner by the project before her for at her advanced age the strain upon her physical resources of such a journey, undertaken under such emotional circumstances must be very severe It is stipulated we understand, that the visit, which is to last a fortnight, is to be a very quiet one and we may be certain that all possible precautions will be taken to spare her from fatigue

THE NATIONAL DRINK BILL FOR 1899

THE increase in the consumption of drink still goes on Dr Dawson Burns's annual letter setting forth the facts appeared in the *Times* of Feb 27th It excites little attention and is the subject of little comment But the facts are amongst the most significant not to say appalling, of any in a sociological and medical sense One day when the exceptional excitement of the war is over they may receive the attention that they deserve The cost of our alcoholic drinks in 1899 was £162 163 474, as compared with £155 994 019 In other words we spent over such things in 1899 £6 169 455 more than we did in the previous year The particular items of increase were—on spirits, £2 842 998 , on beer, £4 798,745 ; and on wine, £40 797 The estimated expenditure for alcohol per family of five persons for 1899 is £19 19*s* 9½*d* —say £20 The alcohol consumed in the several chief liquors which absorb so large a portion of the nation's income is estimated in gallons as follows in spirit, 25 341 648 , in beer 66 313 938 in wine, 2 499 296 and in cider, &c , 750 000 The consumption of alcohol per head in the different divisions of the country is as follows England, 2 51 gallons , Scotland, 1 84 , and Ireland, 1 60

THE HOUSING OF THE WORKING CLASSES PROBLEM

A WRITER in the current number of the *Contemporary Review* points out that the housing problem becomes acute about once in every decade and suggests as a reason for this periodicity that what is done at each explosion as it were suffices for ten years We rather question this inference It would seem on the whole more probable that in relation to this vast and very difficult question there is some sort of systole and diastole of the philanthropic and utilitarian spirit and that in the past at least the diastolic period has been somewhere approaching a decade Be this as it may, there are distinct indications that another acute phase is upon us, and that when the ring of battle is over and the public have adapted themselves to the income tax we may find a reaction in a housing of the working classes atmosphere The Bill to amend Part III of the Housing of the Working Classes Act, 1890, which has been introduced by the President of the Local Government Board is in itself a sure and certain sign that the matter presses, and the Bill introduced by Mr Steadman and Mr John Burns shows us whither perchance we may be tending In certain particulars Mr Chaplin and Mr Burns see almost eye to eye The one proposes that for the purposes of Part III of the 1890 Act a local authority may establish or acquire lodging houses for the working classes outside its own area the other that a local authority may acquire land outside its own area Mr Burns, however, goes many steps further He proposes that for the purposes of Part III a local authority may after six months notice acquire compulsorily land at any price representing 25 years purchase based on the annual value assessed for taxation Money too, is to be forthcoming upon easy terms and the Public Works Loans Commissioners are to grant loans which are to bear interest at a rate *not exceeding 2 per cent* the repayment of such loan to extend over a period of *100 years* To prevent anything approaching an undue return on money laid out there is to be created in the district of every local authority a "fair rent court " which is to consist of three members and in London there are to be six such courts Of these three members one is to be elected by the local trades council consisting of working trades unionists, another by the local chamber of commerce, and the third is to be nominated by the two members above referred to or if they disagree, by the Board of Trade This "court in estimating a fair rent shall, " after allowing for average expenses of repair and management, allow not more than a clear profit of 3 per cent per annum on the original outlay The promoters of the Bill propose, too, that in any scheme under the 1890 Act the space to be provided for each adult shall be no less than 600 cubic feet the same allowance to be provided in all common lodging houses This last provision shows a wholesome tendency

INCREASING PREVALENCE OF CANCER IN THE UNITED STATES

DR G BETTON MASSEY of Philadelphia has published a valuable critical and statistical article illustrated with many charts and devoted to the above subject [1] According to several writers an increase in the prevalence of cancerous affections is shown by mortality statistics of the past 30 or 40 years Concerning the prevalence of cancer it may be noted that it is said to be extremely rare in such countries as Arabia East Central Africa, Iceland, Jamaica, Mauritius and Persia [2] The testimony as regards civilised countries is both ample and startling . The figures given by the Registrar General's Report for England and Wales during 31 years [3] shows that there has been an increase from 38 5 persons dying from cancer in 100 000 living population in 1864 to 75 5 dying from cancer in 100 000 living in 1895—In other words the ratio of the mortality from cancer has almost exactly doubled in England and Wales during the 31 years preceding 1895 According to figures collected and published by Dr Herbert Snow [4] a corresponding increase may be asserted for Scotland and Ireland The condition of affairs is also serious in America and in a recent paper Dr Roswell Park [5] has ventured the prediction that "if the present rate of increase of cancer in New York State continues during the next ten years its mortality will become greater than that of consumption typhoid fever, and small pox combined The objections put forward by some writers that the population of great cities is a shifting and changeable quantity which vitiates statistical records is shown by Dr Massey to be inadequate For, assuming the reasonable accuracy of the decennial census returns it may be further pointed out that the statistics are gathered from a large number of American cities in which the registration of the causes of death has been obligatory for many years, that the populations of these cities are, it is true, estimated , but that these estimates have been frequently checked by municipal enumerations As no deceased person can be buried in these cities without certification and registration it is evident that the total deaths from cancer in the statistical tables furnished for each year have but one source of inaccuracy and that is a mistaken diagnosis on the part of the attending physician but this source of inaccuracy must be small indeed When the number of deaths from cancer in each of these cities for a period of years is reduced to the ratio per 100 000 of population and the ratios are represented on graphic charts a glance shows that there is a gradual and sustained increase in the proportion of deaths from cancer. It may be added that Dr. Massey's figures represent *the first compilation made from the registration returns* of the cities mentioned below, and that they are official, having been prepared for him by the statistical officers of the departments of health of each city. These cities include San Francisco, Boston, Chicago, Brooklyn, New York City, Philadelphia, New Orleans, St. Louis, and Baltimore. It appears from these tables that the greatest increase has occurred in the city of San Francisco, where the ratio has crept up from 16 5 cases in 100,000 of population in 1866, to 103·6 per 100,000 in 1898. "This enormous increase of more than six times as many cases in 32 years is deserving of special attention." The city of Boston shows the next most considerable increase, the ratio of cancer mortality having trebled in the 24 years between 1863 and 1887. After the latter date there was a temporary decrease, followed by a tendency to increase to the present time. In Chart VIII. Dr. Massey has combined the figures representing the cancer mortalities of the seven largest American cities, exclusive of Chicago, the records of which city were probably considered by its officials of too recent date to be valuable in this connexion. The 28 years from 1870 to 1898 have been included in this chart which must therefore be a reasonably accurate record of the cancer death-rate under modern conditions of diagnosis. The chart shows that in these seven great American cities, with a combined population of 8,207,464 in 1870, the ratio of deaths from cancer was 35 4 per 100,000 living persons. In 1898 the population of the same cities was 17,035,235, and the ratio of deaths from cancer was 66 4 per 100,000 living persons, showing that the ratio of mortality from cancer in these cities had almost doubled itself in the comparatively short time of 28 years. Dr. Massey carries on the curve of mortality into the future by the method of extrapolation[6] and concludes that "if the same mean rate of increase is maintained until the year 1910 there will be an average of 80 deaths in each city in that year to 100,000 living persons." From a careful consideration of the prevalence of cancer among the urban and rural populations it is shown that there must be at the present date about 100,000 victims of cancer in the United States. And this great army of sufferers is by no means made up of the aged and infirm. "The greater number of victims are attacked in the prime of life and while in the possession of vigorous bodily powers—some indeed, even in youth." Dr. Massey dwells on the need for further investigation and research into the causation and the mode of propagation of cancer, and he points out that there is at present but one State laboratory of research and one special cancer hospital, and that means and appliances should be extended for the study of the disease and for combating its present serious increase in the United States of America.

THE METEOROLOGY OF BEN NEVIS.

BEN NEVIS being the highest peak in the British Isles the observations taken at the observatory on its summit (4407 feet above the sea-level) present some peculiarities not found in those taken at ordinary altitudes. When the published observations, which began to appear in 1884, had been brought down to 1897 it occurred to Mr. J. Y. Buchanan that it might be useful to study the meteorological phenomena observed during clear weather on the one hand and during fog on the other. He has now completed this task and his paper on the subject is printed in Vol. xxxix. of the Transactions of the Royal Society of Edinburgh. A separate reprint, consisting of 42 pages of letterpress and eight plates of graphic curves, is published by Messrs. Robert Grant and Son in Edinburgh and by Messrs. Williams and Norgate in London. The period covered by Mr. Buchanan's paper is from Jan. 1st, 1885, to Dec. 31st, 1897, and it was a task of great labour to sort these 13 years into periods of clear and of foggy weather, leaving out all days of mixed weather. The results with regard to rainfall, barometric pressure, tension of aqueous vapour, and temperature were as follows. In continuous clear weather it practically never rains on the mountain at all. In continuous foggy weather, on the other hand, the average daily rainfall is almost exactly one inch. There is a large and continuous excess of barometric pressure in clear weather over that in foggy weather. In foggy weather the vapour tension is that of saturation at the temperature of the air and the variations are slight. In clear weather the variations are considerable. The mean temperature of the year is 3·57° F. higher in clear weather than in foggy weather. The fog which characterises the climate of the mountain is nothing but cloud under another name. The observatory of Ben Nevis, in fact, furnishes a record of the meteorology of the clouds and in this respect it is unique.

THE INEBRIATE AND THE CERTIFIED REFORMATORY.

COMMENTING more than a year ago[1] on the Inebriates Act of 1898, we pointed out the difficulty that might arise in the practical application of it, not from any failure of judges or magistrates to appreciate the new powers given to them but from the lack of reformatories, the institution of which the Act seemed to regard as assured. When we wrote the Home Secretary had intimated that the immediate provision of a State inebriate reformatory was not to be expected, but even if one had been prepared before the Act came into force it would only have accommodated a small number of those to whom the new law applied. The habitual drunkard convicted on indictment of a serious offence was to be committed to the State reformatory or to the certified inebriate reformatory willing to take him in, while the drunkard convicted four times within 12 months of certain scheduled offences, such as being found drunk in a highway, had only the certified inebriate reformatory open to him, subject to the same proviso that the managers should be willing to receive him. In considering the matter with the section before us which enables, but does not compel, county councils and similar bodies to contribute to or maintain reformatories or to defray the expenses of detention of any person in such an institution, we perhaps needlessly hesitated to express in plain terms what we intended to suggest—that to leave to public or private benevolence the building and organising of these institutions was to invite delay in putting into force an experimental Act which was capable of doing a considerable amount of good and of preventing the recurrence of charges in our police-courts in the manner associated with the name of the late Jane Cakebread. We, however, said: "Obviously those reformatories which county and borough councils institute will only be willing to receive inmates from contributing districts, while private ones may be far to seek; and, again, public bodies may wait to take steps until the resources of private benevolence within their jurisdiction or within easy reach of it have been exhausted." The state of things which has, in fact, arisen is shown by what passed at the hearing of a charge of drunkenness the other day by Mr. Fordham, a London magistrate. The prisoner had been remanded in order that it might be ascertained whether there was any institution to which she could be sent, and the court missionary, who had corresponded with the Government inspector under the Act, had received from him the following reply: "I am afraid I cannot help you. I am at my wits' end to answer half the queries from London police-courts just now. Duxhurst is, I believe, full. Ashford being Roman Catholic is out of it, and Bristol won't take London cases into either of their reformatories. The London County Council's own place will not be ready till April. Until that time I fear it means a block. Can you not address the same question to the clerk of the Inebriates Committee of the London County Council? It might spur them up." In explanation of the attitude of the Bristol reformatories towards London inebriates the warden of the Royal Victoria Homes at Brentry, near Bristol, writing to the *Pall Mall Gazette*, has since stated that the accommodation in his homes is ample "if only the London County Council saw its way to do as other county and borough councils in England have done—e g., contribute as the Act provides." We take this to mean that the London County Council has refused to pay for London patients being treated at Brentry, as it would hardly be expected to contribute in the ordinary sense while it was itself about shortly to open a reformatory of its own. Whatever the cause of this attitude of the London County Council may be its result is deplorable, if it is anything like that which is stated in the letter of the Government inspector, a gentleman not likely to exaggerate. Apart from the desirability of applying without delay the remedy provided, the County Council could only have gained by experience in watching the treatment of its inebriates in the Victoria Homes or any other homes in which it might have been able to come to terms with the management. We wish every success to the Council's home, which, it is said, will be opened in April, but if London, which should lead the kingdom in such matters, is so tardy what can be expected of other districts? Perhaps in due course and after experiment local bodies will be compelled to provide for their inebriates instead of being merely permitted to do so. At present, as far as we can see, they can either refuse to take any steps at all with regard to them, or if they do so by building a home at the expense of their locality, the managers can still at their discretion refuse to receive the inebriate who in the view of a magistrate within the district is a proper inmate for their reformatory.

---

[6] To extrapolate is "to obtain by extending a series of numbers by an empirical law deduced from the observed law of progression of the numbers."

[1] THE LANCET, Feb 11th, 1899, p 392.

THE COLLEGE HOSPITAL, PIETERMARITZBURG.

IN the *Times of Natal* of Feb. 9th, 1900, appears a correspondence between Major H. Heath, Assistant-Adjutant-General, Lines of Communication, and the editor of the *Times of Natal*, Mr. C. H. Lepper. There is also a copy of a report signed by Sir William Stokes who inspected the above hospital on Feb 5th in consequence of certain statements made in the *Times of Natal* on Feb. 3rd in reference to the condition of the management of the hospital and the treatment of the wounded therein. It appears that a member of the staff of the *Times of Natal*, Mr. Harrison, went to the hospital on Feb. 2nd and on Feb. 3rd there was published in the paper an account either written by him or founded upon information supplied by him. The article was, according to Major Heath, headed "Serious Complaints by the Wounded; Wounds Undressed since Spion Kop." This battle, it will be remembered, was fought on Jan. 24th. Therefore the allegation was that the wounded had been practically left with their wounds undressed for a space of 10 days. Sir William Stokes in his report states that he found on inquiry that every man wounded at Spion Kop allowed that his wounds had been attended to at the various hospitals on the way down from the front and that they were also attended to on arrival at the College Hospital either on the same night or next morning. Confronted with this statement the editor wrote to Major Heath saying that he was prepared to publish a statement to the effect that "we desire to make plain that the non-dressing of wounds mentioned (in the article of Feb. 3rd) referred solely to absence of treatment after arrival at the hospital." Mr. Harrison, the member of the staff of the *Times of Natal* mentioned above, made the following statement about three cases: (1) That a man wounded in the cheek and leg had never been dressed since he left the battlefield; (2) that a man with an injured eye could get no lotion; and (3) that a man who had been shot through the thighs had had no sleep for six nights and had had no attention beyond the placing of a plaster over the wounds and a pillow under his knees. At the official inquiry, at which the Commandant of Pietermaritzburg, Lieutenant-Colonel Johnston (principal medical officer), Sir William Stokes, and Mr. Harrison were present the first man said that he was examined on the field, dressed at Mooi river, and passed by the medical officer on arrival at the hospital. The second patient, the man with the injured eye, stated that his wound had not been attended to at the hospital up to Feb. 2nd. This statement is made by the editor in an "appendix" to his letter of Feb. 8th. Mr. F. W. Gray, however, who accompanied Mr. Harrison, gives a different version in a sworn declaration. He there says that the medical officer saw the second patient and ordered lotion, but there was none in the hospital, so a bandage was applied. Sir William Stokes reported that atropin drops were ordered and supplied. The third patient, the man who was shot in the thighs, denied Mr. Harrison's statements point blank. The editor finally maintains that he is quite content to leave the matter to the judgment of the public. We think it is about the best thing he can do. But the honest course would be to allow that, to put it mildly, he and Mr. Harrison had made a mistake.

PULSATING EMPYEMA.

IN the February number of the *Albany Medical Annals* Dr. J. L. Archambault has published a case of this rare affection, of which, in 1889, Osler could collect only 42 cases. The most complete study of the subject is Comby's, which appeared in 1891 in the *Archives de Médecine*. On this the following description is largely based. Under the term pulsating empyema two different conditions are included. In one the pulsations cover a wide area of the thorax; in the other they are confined to a fluctuating tumour which communicates with the effusion. The pulsating tumour is not always single, there may be two. Its most usual position is between the second and sixth ribs in front, outside the mamma, but the pulsating area may, as in Dr. Archambault's case, be in the lower axillary region. It may also be distant from the thorax; a case is reported where it was in the lumbar region. Pulsating empyemata are almost always left sided. The recognition of the pulsation is important, for it shows that the effusion is purulent. Pulsating empyema has often been mistaken for aneurysm—an error which leads to the delay of necessary intervention. The presence of a large effusion, the situation of the pulsation, and the absence of a murmur, thrill, or pressure symptoms, differentiate the condition from aneurysm. Again, a pulsating abscess in the præcordia may be confounded with pulsating empyema. For example, a girl, aged four years, had for several months pain in the region of the heart. A tumour appeared in the præcordia and increased rapidly. It showed pulsation synchronous with the pulse and was slightly reducible. The overlying skin was red, tense, thin, and hot. There were no signs of pleural effusion and no cardiac murmurs. Puncture gave exit to pus. On incision a [illegible] at the junction of the sixth costal cartilage and rib, making a communication between the superficial abscess and another beneath the thoracic wall. The rib was denuded. There were evidently costal periostitis and "shirt-stud" abscess. The posterior pocket must have been in contact with the pericardium. Sinuses persisted for about three months, but finally cicatrisation took place. In pulsating empyema if the pleural cavity be emptied by aspiration pneumothorax usually results, for the atelectasis of the lung is such that it cannot dilate to fill the vacuum. The heart is deviated to the right and fixed there by adhesions. Pulsating empyema is essentially chronic and if left to itself is usually fatal. Dr. Archambault relates the following case. A boy, aged six years, had scarlet fever in April, 1893. During the last stage of the fever cough appeared; after recovery it persisted and grew worse, and pain in the side and dyspnœa occurred at times. Advice was therefore sought in August. The skin was almost livid and the dyspnœa was intense. A pulsating, soft, and fluctuating tumour of the size of the palm was situated over the left seventh, eighth, and ninth ribs, about midway between the axillary and scapular lines. There were signs of a large left pleural effusion. Dulness extended anteriorly nearly to the clavicle, below which there was Skodaic resonance. The apex beat was to the right of the sternum. Aspiration at the angle of the scapula showed the presence of pus. An operation differing from that for ordinary empyema only in that the incision was made in the centre of the fluctuating area, penetrating the pleura between the eighth and ninth ribs, was performed. Progress was satisfactory and a month after operation the pleural cavity had contracted so that it admitted only one fourth of the quantity of liquid which had been used for irrigation. The heart had moved half way towards its normal position, the side was slightly depressed and flattened, and some respiration was present. In 1899, when the child was 12 years old, the chest was symmetrical and expanded well; no abnormal signs were present. The heart was hypertrophied from valvular disease and the apex beat was outside the nipple line. This case is important because it is opposed to the teaching of Comby that in pulsating empyema the lung is permanently contracted.

MEMORIAL TO THE LATE MISS MABEL ELIZABETH WEBB, M.B. LOND.

AFTER the annual meeting of the Governors of the Royal Free Hospital on Feb. 28th, the new museum and laboratories recently added for the benefit of the Medical School attached to the hospital were formally opened by Lady Reay, C.I. This addition has been made as a memorial of the late Miss Mabel Webb, who was curator of the museum and assistant pathologist to the hospital until her sudden death on Oct. 28th, 1898. She had been curator of the museum for two years and realising how much pathological work was hindered at the hospital from want of space she had originated and designed the extension of building which has now been completed to perpetuate her memory. The influence of Miss Webb's fine character and personal charm upon all with whom she came in contact was such that before definite arrangements for a memorial had been made the students who worked under her had spontaneously raised a fund of money for such a purpose. The medical staff of the Royal Free Hospital and its lay governors were no less impressed by their late curator's service to the hospital and good influence generally, and thus from the willing subscriptions, of colleagues, students, and friends, bountifully supplemented by the generosity of Miss Webb's mother, a memorial of the most appropriate kind has been raised to her memory. The new floor contains a museum with shelves for 6000 specimens, a laboratory for the use of the curator and medical staff, and an assistant's room. The room below, which in Miss Webb's day had to answer all these purposes and also accommodated the curator's classes, is now devoted entirely to the last purpose. A bronze memorial tablet which is to be placed in the museum bears the following inscription: "This building was enlarged by the family and friends of Mabel Webb, M.B. Lond., Curator to the Museum of this Hospital from 1896 to 1898, to honour her memory and to carry out a scheme originated by her for the improvement of the Pathological Department. Through devotion to duty and pursuit of high ideals of work and conduct her term of service here was in an unusual degree fruitful of good. *Beati mundi corde: quoniam ipsi Deum videbunt.*"

METROPOLITAN BRANCH OF THE BRITISH DENTAL ASSOCIATION.

THE annual dinner of this association was held at the Hotel Cecil on March, 3rd, the President, Mr. Ashley W. Barrett, M.B. Lond., M.R.C.S., L.D.S. Eng., being in the chair. The attendance was large and included many guests. The loyalty of the audience found felicitous expression in the President's speech and in the National Anthem, which was twice sung. The President also proposed "The Association and the Metropolitan Branch." The branch is in a prosperous state and seems to be very efficient for the promotion of harmony and coöperation. A very pleasing part of the entertainment was furnished by the songs by Mr. J. Clulow and Mr. R. H. Manning, and the recitations by Mr. Percival Reed, which were nearly all encored. Dr. Glover, in responding for the guests, touched on the wonderful development of dentistry as a profession since the Act of 1878; and by way of illustration alluded to the fact that the Government had sent out Mr. Newland Pedley and a staff of dentists to help to complete the arrangements for the medical comfort of our brave soldiers—a refinement of care which distinguished the present from all previous wars.

BERI-BERI IN THE STRAITS SETTLEMENTS.

IN his annual report on the Straits Settlements civil hospitals for the year 1898 Dr. Max. F. Simon, the principal civil medical officer, says that the estimated population of the whole of the Straits Settlements for that year was 592,587, as compared with an estimated population of 580,563 for 1897. The number of births that were registered in 1898 was 12,781 and the number of deaths registered was 18,032, giving birth- and death rates per 1000 of population of 21·57 and 30·43 respectively. The colony was very free from epidemic disease during the year. Only nine deaths from cholera were registered in Singapore and 39 in Penang; no cases occurred in Province Wellesley or Malacca. The deaths from small-pox were 46 in Singapore, two in Penang, one in Province Wellesley, and 23 in Malacca. There were considerably fewer cases of beri-beri admitted into all the hospitals of the colony during 1898 than during 1897, the admissions numbering 1329 as against 2095. The disease also appears to have been slightly less fatal, 420 deaths having occurred (a percentage on admissions of 31·6) in 1898, as against 692 (a percentage on admissions of 33·28) in 1897. The death-rate from this disease was, as usual, higher in Singapore than in any of the other settlements. There appear to be upwards of 16 hospitals in the colony, and the whole number of admissions to them for 1898 was 23,662 with 3296 deaths. The diseases which caused the greatest number of admissions to hospital were as follows: dysentery, 875 admissions, 369 deaths; malarial fever and cachexia, 2174 admissions, 158 deaths; beri-beri, 1329 admissions, 420 deaths; venereal diseases, 2594 admissions, 121 deaths; rheumatism (acute and chronic) 1438 admissions, three deaths; diseases of the digestive system (including diarrhœa), 1938 admissions, 585 deaths; and diseases of the skin, 4058 admissions. In Tan Tock Seng's hospital for paupers in Singapore the number of cases of beri-beri occurring among patients who have been admitted for other diseases has attracted the attention of the Government. In his report on the lunatic asylum Dr. W. G. Ellis, the medical superintendent, states that beri-beri has been even more prevalent than in 1896 and 1897, and unless the better ventilation of the lower levels and the use of a small hospital to be built on the sea coast prove more satisfactory than former attempted remedies the question of removing the whole asylum to some other site must be considered. In 1896, with an average daily number of 233 patients, there were 85 deaths, 40 of which were from beri beri; in 1897, with an average daily number of 228, there were 81 deaths, of which 48 were from beri-beri; and in 1898, with an average daily number of 208, there were 95 deaths, of which 55 were from beri-beri. Seven attendants suffered from the disease and two of them had to leave the service on account of persistently recurring attacks; the other five made good recoveries. With respect to Singapore Prison Dr. J. Leask, the surgeon in charge, mentions that for a period of 12 years—namely, from 1885 to 1897—only two patients were treated for beri-beri, one of whom was suffering from it at the time of admission. In November and December, 1897, three cases occurred, and in 1898 there were 124 cases, of which 14 appeared from the beginning of January to the end of September, 10 in October, 78 in November, and 22 in December. Only one death was due to this cause in 1898. Strychnine in large doses was the principal treatment, commencing with five-minim doses and rapidly increased to 16 minims every four hours. In no case was the physiological action of the drug observed. Digitalis was given in all cases. Diuretics and purgatives were largely used, elaterium being found the most satisfactory of the latter. For dyspnœa solution of nitro-glycerine in frequently repeated doses acted admirably.

A GOOD RECORD IN OPERATIONS FOR CATARACT.

DR SAMUEL THEOBALD of Baltimore has recently published in the form of a pamphlet a report on 100 consecutive cases of cataract extraction. They were certainly not selected cases, since they include two eyes on which iridectomy had been previously performed for glaucoma, two in which the lens was dislocated through injury, one of high myopia, and various cases affected with choroiditis. The section was in all instances made at the sclero-corneal junction, and in many instances a small conjunctival flap was made. In the majority of instances the extraction was combined with iridectomy, either performed at the time or effected by a preliminary operation. Still a considerable number of cases, 19 in all, were done without iridectomy. Cocaine was used as an anæsthetic in 89 cases, chloroform was administered in six, and no anæsthetic was given in the rest Careful antisepsis was practised In the after-treatment no bandage was applied, but the eyes were closed with strips of isinglass, or in restless patients a pad of cotton-wool was placed over each eye and retained by similar strips. The patient was kept in the bed where he was operated upon for three days, after which the dressings were changed and a daily instillation of a solution containing four grains of atropia and ten grains of boric acid to the ounce of water was applied. As a matter of routine 20 grains of sulphonal or trional were given to the patient on the evening of the operation. The results are such as Dr. Theobald may congratulate himself upon having obtained, and are better than he could have anticipated considering that the cases were consecutive and not selected. He counts vision $\frac{20}{100}$ to $\frac{20}{200}$ as successes, and of these to have had about 90 per cent.—a very satisfactory number. There were two losses from suppuration. The other failures were from collapse of the globe consequent on loss of fluid vitreous, detachment of retina, and choroido-retinal changes. No losses occurred amongst those in whom the simple operation was performed.

CHELSEA CLINICAL SOCIETY.

Two special meetings of this society will be held in the Holy Trinity Parish-hall, Pavilion road, Sloane-square, S.W., on Tuesday, March 13th, and Tuesday, March 20th, at 8.30 P.M. At these meetings the annual clinical debate will be held and the chosen subject this year is the Treatment of Rheumatism, with special reference to Prophylaxis and Cardiac Complications. The debate will be opened on March 13th by Dr. William Ewart and the following among other speakers are announced to take part in the discussion: Dr. T. J. Maclagan, Dr. A. E. Sansom, Dr. Donald Hood, Dr. David B. Lees, Dr. Archibald Garrod, Dr. Pye Smith, Dr. R. Caton, Dr. Burney Yeo, and Dr. Isambard Owen. Sir Richard Douglas Powell, Bart., will give a closing address on March 20th. The meetings will be open to all members of the medical profession on presenting their cards. The special subject for debate is to be considered under the following aspects. On March 13th: (1) the general factors bearing upon the Prophylaxis of Rheumatism: the need for organised investigation; (2) the general, medicinal, and dietetic treatment of the acute attack and of the rheumatic tendency; and (3) the relative anti-rheumatic value of various drugs and modes of treatment. On March 20th: (1) the Special Prophylaxis against the occurrence or aggravation of Rheumatic Valvulitis: can valvulitis be prevented or cured at its early stage? (2) the methods which have been advocated for the prevention or cure of the valvular affection; (3) the alkaline treatment and its varieties and the salicylic treatment and its varieties: should they be combined? and (4) the unfulfilled indications and requirements.

PLAGUE IN THE ARGENTINE REPUBLIC.

ON Jan. 26th the existence of bubonic plague in the city of Rosario was officially declared by Government decree and on the following day the city was completely isolated from the rest of the country, all railway and river traffic being suspended. Troops of the line formed a cordon by land and torpedo destroyers and gun-boats guarded the river, which is many miles broad. The authorities hope that this complete investment by sea and land will prevent the escape of those infected by the terrible bacillus, which is, however, reported to be already in Buenos Ayres, the capital of the republic The existence of plague in Rosario has been suspected for some time and bacteriological investigations have been carefully carried out, but the Government hesitated to declare the fact officially—a policy which was a source of embarrassment to foreign ministers and consuls, who could not obtain from the Argentine Government the corroboration requested by their respective governments. Rosario is a large city of 100,000 inhabitants, and as a port it comes next in rank to Buenos Ayres. It is the outlet for the great grain region of Santa Fé and every year sends to Europe over 1,000,000 tons of wheat, maize, and linseed, as well as thousands of tons of wool. It is also a port of call for all vessels going to, and returning from, Paraguay, where bubonic plague has been present for some months past but not actually in epidemic form. In fact, nowhere along the South American coast has the plague taken a strong hold, a few isolated cases at Rio Janeiro, Santos, São Paulo, and Asunción (Paraguay) being the record up till now. This outbreak in Rosario is limited to some wharves along the river side where hundreds of thousands of bags of wheat and maize are stored, and measures have already been taken to isolate this produce and the workmen, 280 in number. Both Rosario and Buenos Ayres are well able to deal with the plague or any other epidemic. They have a constant and abundant water-supply, are well drained, and there are no slums, such as are in New York, Glasgow, or London. The municipality of Rosario has taken some practical measures. Free baths have been opened, and all dustmen, sewage-men, and scavengers in municipal employ are obliged to have baths on finishing their day's work. The ordinary house refuse is to be removed by the dustman twice a day in the poorer neighbourhoods (being the height of summer the average temperature is 90° F. in the shade). Daily inspection of the common and larger lodging-houses is being carried out; and last, but certainly not least, the immense ponds of stagnant water which still exist as a danger and eyesore between the long series of docks and the streets proper of the city are to be immediately filled up—no light task, as it will require many millions of cubic feet of cinders, sand, and other materials. As will be seen from the letter of our Rome correspondent Italy is specially interested in the outbreak owing to a large percentage of the foreign residents being Italian by nationality.

THE ANNUAL REPORT OF THE COAL-SMOKE ABATEMENT SOCIETY.

THE report of the Coal-Smoke Abatement Society for 1899 has just been issued. Although the society has been in existence for little more than a year, and owing to lack of funds can only support one inspector, yet it has achieved excellent results. Mr. Petty (the inspector) has since May, 1899, reported 1250 observations. In 680 instances official complaints have been made to the vestries which led to statutory notice being given in most cases and to legal proceedings being taken in 62 cases. In 30 of these the nuisance was entirely suppressed and in 32 cases it was much lessened. Summonses were taken out and convictions obtained in 34 cases. We are glad to see that a Smoke Amendment Bill is to be introduced by the London County Council. The report points out that the greater part of the evil—namely, the emission of smoke from the chimneys of private dwellings—remains untouched, but that a technical committee has been formed to examine and report upon the means of preventing smoke from private dwellings without extra expense for fuel. There is no doubt that the fogs of late have been much less smoky—fog in London can never be averted owing to climatic conditions—but it is possible to ensure that it shall be clear. In the last dense fog which we experienced this improvement was specially noticeable, a fact upon which we commented at the time.[1] The Coal-Smoke Abatement Society has done excellent work, and if by its efforts the magistrates can only be brought to understand, as in many instances they have been, that the plea of "No Welsh coal" is no excuse in the eye of the law, we may hope to see the atmosphere less smoky this year than even during that which is past.

GENERAL LEONARD WOOD, GOVERNOR OF CUBA.

THE announcement that the President of the United States had appointed General Wood Governor of Cuba met with the unanimous approval of the American people. Of all the officers of the United States Army who served in the Cuban campaign no one fulfilled his military duties with greater credit than the man who before the Spanish-American war was an assistant surgeon in the regular army. It was through the influence of his friend Theodore Roosevelt, now Governor of New York State, but who at the time of the outbreak of the war with Spain was assistant secretary of the navy, that Dr. Leonard Wood was placed in command of the famous "Rough Rider" regiment. But although General Wood proved himself a good soldier it is as an organiser and sanitarian that he exhibited his genius. The condition of Santiago when he assumed command of that province could scarcely have been worse. Pestilence and famine were abroad everywhere and to the city of Santiago itself even more than to Havana might the term of "sink-hole" have been aptly applied. General Wood immediately organised and placed on a proper working footing an efficient sanitary system, at the same time insisting that his orders should be carried out to the letter. Owing to this vigilance and energy the death-rate of Santiago was decreased 75 per cent. in six months. Yellow fever, which in its season used to decimate the population and which was dreaded alike by white men and natives, was held at bay and no serious outbreak occurred. But looking after the physical welfare of the people was by no means the extent of General Wood's labours. He formed an effective police force, the members of which were chiefly recruited from the natives. He organised schools and set on foot a scheme of school inspection. Parents were compelled to keep their children clean, the latter not being allowed as in former times to roam the streets. Houses were inspected and if not found in a hygienic state were disinfected and their occupants punished. Precautions were rigidly enforced on the slightest indication of the appearance of infectious disease. In fact, every known measure calculated to render a city which was notorious for its filth and disease a healthy place of residence was thoroughly carried out. The results were, as before mentioned, almost magical and furnish yet another instance of the effects of sanitary methods carried out with a strong hand. The prediction may be safely made that General Wood will regenerate Cuba in the same manner as the British have regenerated Jamaica and that in the course of time yellow fever will be exterminated in the former island.

THE ABATEMENT OF KAKKÉ IN THE JAPANESE NAVY.

DR. TATSUSABURO YABE, principal medical officer in the Imperial Japanese Navy, contributes a short article under the above heading to the *Archives de Médecine Navale* for January, 1900. Not long ago *kakké*, or beri-beri, was the most prevalent malady in the Japanese fleet, at times absolutely paralysing action, just as formerly scurvy used to behave in European squadrons. In 1882 during the Corean expedition, and about the same date in a fleet off the coast of South America, *kakké* placed between 30 and 40 per cent. of the total strength *hors de combat*. "At the commencement of the eighteenth century, continues Dr. Yabé, "the English Admiral Flosier (*sic*) *en route* for the East Indies at the head of seven ships of the line, had he not the pain of losing his crews twice over by scurvy, and did he not himself die broken-hearted?" Scurvy was at length mastered by means of prophylactic measures—they gave the men fruits, fresh vegetables, lime-juice, and lemonade; *kakké* was brought under control by amelioration of the rations—an innovation due to Mr. Kanébiro-Takaki. Scurvy and *kakké* resemble each other by the uncertainty in which their etiology is enveloped. They are said to be epidemic diseases, but as yet the specific microbes have not been discovered. Mr. Takaki believes that *kakké* is a disease of nutrition, and although Dr. Yabé cannot share the belief he nevertheless freely acknowledges the beneficial results that have attended on the prescriptions of the eminent creator and organiser of the Japanese Naval Medical Service. During the sexennial period 1878-83 the average percentage[1] of sickness from *kakké* was 32 5 and there were 246 deaths. In February, 1884, the Takaki ration was introduced, when at once the disease began to disappear from the navy. In 1885 the percentage was 0 59 and during the next eight years it averaged only 0 02. From 1885 to 1893 inclusive not a single death from *kakké* took place. In 1894, during the war with China, two fatal cases occurred, and the following year there was one, but the percentage of *kakké* sickness for the biennium was only 0 19. Dr. Yabé thinks that excessive rice-eating predisposes to *kakké*, whereas barley, and especially pearl-barley—which has long been a favourite article of food amongst the Japanese peasantry—acts as an almost never-failing prophylactic. It was while there was dearth of barley in the Chinese campaign that *kakké* committed its ravages.

---

[1] THE LANCET, Oct 28th, 1899, p 1183.

A MEETING of the Hunterian Society was held on Wednesday, Feb. 28th, at the London Institution, the new President, Dr. Dundas Grant, presiding. The second Hunterian Society's Lecture was delivered by Mr. C. Mansell Moullin. A vote of thanks to the lecturer, proposed by Mr. J. S. E. Cotman, and seconded by Dr. F. J. Smith, concluded the proceedings of the evening. We hope to publish the lectures in an early issue of THE LANCET.

MORE replies to our circular letter to the profession concerning the Midwives Bill have come in during the week, and about half the constituency have registered their views with us. The proportion of five to one against the Bill is maintained, and the figures may be taken to represent the state of professional feelings.

THE annual general meeting of the Medical Defence Union will be held on Tuesday, March 13th, at St. Martin's Town Hall, London, W.C., at 4 P.M. The chair will be taken by Dr. W. S. A. Griffith, the President of the Union.

WE regret to record the death in his seventy-second year of Dr. William Marcet, F R S , which took place at Luxor, Egypt, on March 4th. He had been in failing health for some time.

FORMS have been issued to be filled up by English medical men proposing to be present at the International Conference on Pulmonary Tuberculosis to be held at Naples on April 25th next.

THE WAR IN SOUTH AFRICA.

THE news of last week, which has changed the whole aspect of the war in South Africa, was received with exultation throughout the British Empire. When we consider what Lord Roberts has gone through in his long and distinguished military career, his age, and the great sorrow that had befallen him in the loss of his son, his response to what he regarded as the call of duty was a noble display of patriotic self sacrifice. Apart from the great military services which he has rendered in this war the judgment, tact, and urbanity which he has displayed in dealing not only with his Boer foes but with the colonial troops and all who have been brought into contact with him have been conspicuous

As regards Ladysmith, the news of its relief was well calculated to give immense satisfaction in the state of nervous tension which had existed in the public mind from the time that we had all heard that its garrison was "very hard pressed." The topographical obstacles which had to be overcome in its relief were of the most formidable kind, in the face of which and a succession of Boer entrenchments General Buller's relieving force had repeatedly recoiled only to advance again with splendid determination and gallantry until their efforts were finally crowned with complete success. Of all this, however, there is now no need to tell. When the history of this war comes to be written the siege and relief of Ladysmith will occupy a proud place in our military history. Its relief was a most arduous undertaking and, considering the relatively small force that had to accomplish it and all the attending circumstances, the highest credit is, in the opinion of competent military judges, due to Sir Redvers Buller's military capacity, judgment and determination, in having accomplished it with a loss which, although heavy, was, all things considered, really less than might have been anticipated.

The facts connected with the siege of Ladysmith and its defence for four months under Sir George White speak for themselves. Every word of General Buller's recent general order congratulating the besieged and his own force is well merited and exactly describes the situation. No one can read the brief record of what occurred there on the eventful entry of the relieving troops without a thrill of pride and without realising the dramatic pathos of the situation. It was this that stirred the heart of all English-speaking people. The news of the successful strategy of Lord Roberts, welcome and all-important as it was, had not these elements; it did not involve the rapid transition from anxiety to joy and the commingling of happiness with grief and pitifulness. Somehow the nation, like the troops, held fast to the conviction that there was a plan of campaign existing in the military mind which had never been lost sight of but was only delayed by exceptionally untoward circumstances and would be forthcoming in due time when the military machine was in proper working order.

The garrison of Ladysmith has had a terrible experience during the siege. Their losses by fighting and bombardment have been considerable, but those resulting from enteric fever, dysentery, and other diseases have been still greater. This is not to be wondered at considering the semi-starvation, the privations, the bad water, the fouled soil, and the overcrowding that existed. The troops were in deplorable plight and bore evident marks of the physical suffering and nervous exhaustion which they had undergone. The town contained 21,000 half-starved inhabitants. Although the actual mortality remained comparatively low until the middle of January the general health of the troops suffered severely from the want of good nourishing food and of essential comforts. As many as 8424 persons passed through the hospitals and the daily average under treatment ranged from 1500 to 2000. There were 1710 cases of enteric fever alone, and 800 cases were under treatment at the time of the relief of the town. Ladysmith has never had a particularly good bill of health and sanitary reputation at the best of times and, as we took occasion to point out almost at the beginning of the war, typhoid fever and dysentery were usually prevalent there at this season and were to be expected. Under all the insanitary conditions which must have been accumulating during the siege and the desirability of removing the troops and the sick from these and the depressing conditions surrounding them, the military authorities have exercised a most wise discretion in evacuating the station as far as practicable, and this has been, and is now being, done. It is, unfortunately, unavoidable that the sick should feel the fatigue and exhaustion of this movement and its attendant discomforts under even the best arrangements; but change of site was essential under the circumstances in their interest and, still more so, in that of the healthy, in order to limit the spread of disease as far as possible. A large number of nurses will be required to attend upon the sufferers from enteric fever and other patients

Speaking generally, the sanitary state of the army in South Africa is fairly satisfactory. The troops actually in the field look sturdy and strong and are in excellent form. There is, of course, a considerable amount of those diseases which are incidental to field service in hot weather, and notably of enteric fever, dysentery, and diarrhœa The enteric fever rate is, as we have said, very high in the besieged garrison at Ladysmith. It is not limited to Ladysmith, however, cases having shown themselves at other stations and among different columns operating in the field. Cases of dysentery also are of frequent occurrence. Hitherto the rapid succession and severity of the fights have occasioned a disproportionate number of surgical cases, but we are afraid that we must expect a progressive increase of sickness as the campaign goes on. Pneumonia and respiratory affections occasionally appear among soldiers from shipboard. The Government has provided for the requirements of the army in South Africa on a liberal scale and with much care and foresight and has thereby prevented a great deal of disease and suffering. The Army Service Corps has proved very efficient and has rendered conspicuous services to the troops. In all these respects, and especially considering the very severe fighting and the arduous nature of the campaign, there is every reason to feel satisfied, especially when the sanitary and medical arrangements of the present war are compared with those of the French expeditions in Madagascar and Tonquin, for example, or with those of the campaign in Cuba.

---

[1] It is not clear whether this percentage refers to strength or to total sick from all causes, but probably the latter is the case.

In congratulating Lord Roberts on the brilliant success which he has so far achieved we do not forget that as medical journalists it is especially gratifying to us to do so, seeing that medical officers have invariably met with considerate appreciation and fair treatment at his hands during the course of his long and distinguished service. It must have been extremely gratifying to the Queen to have received his lordship's telegram just as Her Majesty was leaving Windsor for Netley and to be the bearer of its good news to her wounded soldiers, in whose welfare and comfort Her Majesty has always taken a very keen and sympathetic interest.

Medical Division, War Office, March 7th, 1900.

STATISTICAL METHODS AND THE INDIAN PLAGUE COMMISSION.

AT the close of our notice in THE LANCET of Feb. 24th of the report of the Indian Plague Commission upon Haffkine's Plague Prophylactic we expressed our intention of returning again to a brief discussion of the statistical methods adopted by the Commissioners and by Mr. Haffkine respectively. The method hitherto followed by the latter to express in percentages the reduction in mortality brought about by the use of the prophylactic has been as follows. The number of deaths from plague occurring in the uninoculated portion of a community is ascertained, and from this by a simple arithmetical process is calculated the number of deaths which might have been expected to occur in the inoculated portion of the community if they had died at the same rate as the uninoculated. The difference between this figure and the actual number of plague deaths in the inoculated population is then found and expressed as a percentage of the anticipated number of deaths. An example will make quite clear the process involved and it will be most convenient to use round figures. We may suppose a mixed population of 3000 persons, of whom 2000 are uninoculated and 1000 inoculated. We may further suppose that 500 of the former die from plague and 50 of the latter. It is clear that if the inoculated had died at the same rate as those not inoculated 250 of them would have died; but only 50 did so. The reduction in mortality was therefore 200 in actual figures, or 80 per cent. upon the anticipated number of deaths.

The Commissioners have, however, through the greater part of their recently issued report followed a totally different method. They have ascertained the percentage ratio borne by the number of plague deaths in the inoculated to the total numbers of inoculated, and the corresponding figure for the uninoculated. Subtracting the former from the latter the difference is taken to represent the "diminution in mortality in favour of the inoculated." In the hypothetical instance just discussed this method would work out as follows: the percentage mortality in the uninoculated in the case supposed was 25 per cent., that among the inoculated was only 5 per cent. According to the method followed by the Commissioners the "diminution in mortality in favour of the inoculated" would be expressed at 20 per cent.

As to which of these methods is the fairer and more correctly represents the results obtained there can, we believe, be but one reply. The method adopted by Mr. Haffkine is, it may be confidently asserted, not only the fairer but the only correct way of expressing the results. The fallacy involved in the method selected by the Commissioners may be at once shown by a concrete example taken from the pages of their report. On page 55 is a table showing the effect of the inoculations upon the Punjabi Khojas, and on page 58 is another analogous table referring to certain houses occupied by Khojas in Karachi. In the former the uninoculated lost by plague 2 4 per cent. of their number, the inoculated 0 75 per cent., and the difference was 1·6 per cent. In the latter the uninoculated lost 15·7 per cent. of their number, the inoculated 5·1 per cent., and the difference was 10 6 per cent. In each case the Commissioners regard the difference as the "diminution of mortality due to inoculation," and to the ordinary reader it would be open to infer that the inoculations in the latter instance were more efficacious than in the former in the proportion of 10 6 to 1 6, or very nearly as 7 to 1. Yet it will be seen that this was not the case and that *in each* instance the reduction in mortality was almost identical, the inoculated in each group having a percentage mortality something less than one-third of that in the uninoculated. When worked out upon Mr. Haffkine's method this practical identity in results would be at once clearly seen.

The Commissioners take exception to Mr. Haffkine's statement that "one can say in a general manner that the reduction in the mortality produced by inoculation is between 80 and 90 per cent." "Such a statement," they write, "taken apart from the actual figures, might be taken to imply either that inoculation had averted death from 80 to 90 persons (*a*) in every 100 of the total population, or (*b*) in every 100 of the inoculated population, or (*c*) in every 100 inoculated persons attacked, whereas the statement really means that death was averted from 80 to 90 in every 100 of those who, without inoculation, would, judging by the mortality among the uninoculated, have died of plague." This criticism appears to us to be of the nature of hypercriticism. We believe it to be very unlikely that any intelligent person would fall into either of the suggested errors of interpretation, and if Mr. Haffkine's method correctly represents the percentage mortality "of those who, without inoculation, would, judging by the mortality among the uninoculated, have died of plague" it would appear to give a very accurate and fair means of estimating the reduction in mortality brought about by the prophylactic. This end is not attained by the method adopted by the Commissioners, and it would be very unfortunate if the figures dotting the pages of the report, which they call "diminution of mortality in favour of the inoculated," and which vary from 0 1 to 36 4 per cent., were regarded as truly representing the beneficial results of the inoculations.

It is only in the synoptical tables that the Commissioners resort to a more correct method of representing results. In column 10, for example, of the table on page 71 of the report are a series of figures expressing the "ratio of plague deaths among the uninoculated to plague deaths among an equal number of inoculated." This ratio was in Undhera 10 to 1, in Bulsar 3 7 to 1, in Hubli 9 6 to 1, and so on. No possible exception can be taken to this method. It merely expresses the mortality in the uninoculated in terms of that in the inoculated, while Mr. Haffkine's method expresses the reduction of mortality in the inoculated in terms of the mortality in the uninoculated. The two sets of figures are published in the Commissioners' synoptical tables in parallel columns and (apart from one or two obvious clerical errors) they present identical results They are, in fact, the same results expressed in two different ways. This being so, it is not easy to see why the Commissioners should adversely criticise Mr. Haffkine's statistical method of presenting his results when in the end they actually adopt that method, merely expressing the same results in another way. (For example, in Gadag 2 3 per cent. of the uninoculated and 0 6 per cent. of the inoculated died; the ratio of plague deaths among the uninoculated to those among an equal number of inoculated was 3 8 to 1, and Mr. Haffkine's figure for the diminution of mortality in favour of the inoculated is .74. A simple arithmetical exercise will show that these figures, and the same is true for the other places mentioned in the table, are convertible) This being so, too, it is almost incredible that immediately after the synoptical table containing these figures should appear the following remarks from the Commissioners: "This [Mr. Haffkine's] method, though it affords information which is of value to those who desire to ascertain how far the effects of the vaccine have approximated to the ideal standard which would have been attained if all cases of plague had been averted from the inoculated, gives results which are likely to convey a wrong impression to the administrator. It will be seen that whereas the diminution of mortality which was achieved by the introduction of inoculations among the troops at Bangalore amounted actually to 0 8 per cent, it figures, when calculated out according to Mr. Haffkine's method, as 53 3 per cent." Surely the Commissioners cannot seriously regard the former as a fairer statement of facts than the latter? or, indeed, as in any sense a fair statement of facts? "Taken apart from the actual figures"—the criterion of criticism they have themselves applied in judging of the other method—such a statement as the above, that "the diminution of mortality achieved by the introduction of inoculations among the troops at Bangalore amounted actually to 0 8 per cent," *could only mean* that the mortality among the inoculated was to that in the uninoculated as 99 2 to 100. This is obviously an extremely inaccurate statement and one which gives a totally wrong conception of the beneficial results achieved by the inoculations in Bangalore.

We have dwelt at some length upon the adoption by the Commissioners of this erroneous statistical method, in preference to Mr. Haffkine's correct method, as its tendency is to minimise the value of prophylactic inoculation in plague, though the Commissioners have themselves admitted its value and the desirability of encouraging it in every way. It is a blemish of some magnitude on an otherwise careful and valuable piece of criticism.

THE ANNUAL REPORT (1898) OF THE MEDICAL OFFICER OF HEALTH OF LONDON.

III

HAVING dealt in recent numbers[1] of THE LANCET with Parts I. and III. of Mr Shirley Murphy's report, we now come to notice, of necessity very briefly, Part II. of that report, which treats of sundry matters that could not conveniently be included in any of its other sections

Availing himself of certain tables in the last census report which show the proportion of the population occupying tenements of not more than five rooms and living more than two in a room, Mr Shirley Murphy has set himself to investigate the relation of overcrowding to mortality, and especially to phthisis mortality, in each of the sanitary districts of the metropolis. An instructive table is given which shows unmistakeably that there is a close relation between the degree of overcrowding and the proportion of mortality from phthisis, especially where overcrowding is represented by a proportion exceeding a fourth of the population living more than two in a room. The figures, however, do not determine whether the overcrowding is the actual cause of the phthisis or whether the disease by adding to family expenditure or by diminishing wage-earning power leaves less money available for rent and thus brings about overcrowding. Another table shows that the phthisis mortality at each age increases with overcrowding, though not in the same proportion. With unimportant exceptions it appears that the death-rates at the later ages follow the order of overcrowding, the differences between the mortality in the several districts being most marked at those ages at which the mortality from phthisis is the heaviest. This point having been settled Mr. Shirley Murphy proceeds to inquire whether it is in respect of phthisis only that excessive fatality is specially related to overcrowding, or whether, on the other hand, the same connexion exists between non-tuberculous mortality and insufficient air-space in the dwelling.

---

[1] THE LANCET, Jan 27th, p 250, and Feb 17th, p [illegible].

In a previous report[2] Mr. Shirley Murphy submitted evidence proving that although the aggregate mortality from "all causes other than phthisis" follows overcrowding in the same manner as does that from phthisis, nevertheless the several forms of disease differ widely in this respect. The experience of 1898 teaches the same lesson: an interesting chart is appended which shows that in that year the decrease of mortality from phthisis is well marked as the line travels from the most to the least overcrowded districts, but that the mortality from tuberculous meningitis manifests this fall in a much less degree and that from tabes mesenterica even less still. The relation of overcrowding to mortality from the ordinary zymotic diseases is not particularly apparent, while cancer fatality does not seem to be affected in any way by overcrowding. The statistics for 1898 therefore indicate that whilst overcrowding tends to produce excessive mortality from all causes this tendency is especially manifested in the case of phthisis, whilst no such relation can be traced in the case of many other prevalent causes of death. Probably this difference in behaviour may eventually be found to depend on differences in the causation and age-distribution of particular diseases.

In several earlier reports Mr. Shirley Murphy has considered with befitting care the influence which is exerted by school attendance on the spread of infectious diseases. In the present report he reiterates the opinion, often previously expressed, that while the usual exodus from London consequent on school closure in August may be held to explain much of the reduced prevalence of diphtheria and scarlet fever which undoubtedly takes place every year during that month, nevertheless this hypothesis does not account for the whole of the reduction which actually occurs, the residue being attributable, in his judgment, to diminished opportunity for infection at school. With a view of ascertaining the extent to which absence of school children from London may have affected the general prevalence of infectious disease in August he falls back on the statistics of enteric fever as the notifiable disease which may be regarded as less communicable than any other disease of its class from one person to another. As there are now available the statistics of seven years he has taken pains to compare the prevalence of this disease with that of diphtheria and scarlet fever, for although the numbers notified at the separate ages are not large enough to warrant conclusions of a precise character, nevertheless they are sufficient for purposes of comparison. By the help of tables it is shown that whilst there is an actual decrease in the number of cases both of diphtheria and scarlet fever notified in August as compared with the number notified in July, which decrease especially affects children of school age, there is no evidence whatever of similar decrease in the number of notified cases of enteric fever.

Mr. Shirley Murphy next takes into consideration the seasonal variation in age incidence as well as in fatality of infectious diseases notified under the Act. A series of tables are given showing the age-distribution of cases of scarlet fever and diphtheria in each month since 1892. The table relating to scarlet fever shows that the proportion of children attacked under five years of age is greatest at the early part of the year, and that the proportion falls to a minimum in September, subsequently rising again towards the end of the year. There is arrest of the fall in August, due to the fact that children of school age are not contracting disease at school, and children under five years of age therefore constitute a larger proportion of the total cases. The table relating to diphtheria shows that the largest proportion of attacks under five years occurs in March and April and the least in September. As in the case of scarlet fever the proportion of diphtheria attacks under five years of age is unduly high in August—a fact doubtless attributable to the closure of the schools in that month. So much with regard to the incidence of *attacks*. With respect to *mortality* it appears that in the case of scarlet fever this is greatest at the beginning of the year, that it falls gradually until the end of September, and subsequently increases towards the end of the year. The fatality from diphtheria follows much the same course, except that the minimum occurs some two or three months earlier than in the case of scarlet fever. Fatality is necessarily affected by the ages of the patients, but correction for this does not suffice to account for the variations in severity at different seasons which is found to attend attacks by this disease.

In view of the great importance which attaches to the treatment of diphtheria by antitoxic serum Mr. Shirley Murphy's remarks on this subject are full of interest. It appears that, as in previous years, the incidence of diphtheria *attack* at "all ages" was greater in 1898 on females than on males, while the incidence of *death* at "all ages" was greater on males than on females. The *incidence of attack* was greatest on both males and females aged four years, while the *incidence of death* was greatest on both males and females at two years of age. As in previous years, the fatality was greatest among infants under one year old. A table is inserted in the report which shows the variations in the case mortality at the several ages. The marked fall in the fatality at "all ages" and especially at the younger ages in recent as compared with earlier years, is very marked. He therefore suggests the important question, "How far is this fall due to the use of antitoxic serum?"

In the statistical report for 1898 of the Metropolitan Asylums Board there appears a table showing a very remarkable decrease in the case mortality of diphtheria treated in hospital with the help of antitoxic serum during 1895-98, as compared with the years 1888-94, before antitoxic serum was in general use. Mr. Shirley Murphy, however, does not feel justified in attributing the whole of this decrease to the use of the serum, for he shows that a similar decrease has taken place in respect of the hospital cases of scarlet fever within the same period. Apart from the question of treatment there is no doubt that the following circumstances have affected the mortality: (*a*) notification of infectious cases has certainly been more general in the later than in the earlier period; and (*b*) the proportion of diphtheria attacks admitted to hospital has been greater recently than in former years. The first of these changes would tend to reduce the fatality in London as a whole, the second to have reduced the fatality of the hospital cases. He summarises the case thus. 1. There has been a lower fatality both in the case of diphtheria and of scarlet fever in the period 1895-98 compared with 1892-94. 2. Whereas both in 1892-94 and 1895-98 the fatality among scarlet fever cases in the Metropolitan Asylums Hospitals has been greater than among notified cases treated elsewhere, the fatality among diphtheria cases in the Board's hospitals, which in 1892-94 was greater than among home cases, was in the period 1895-98 practically the same at "all ages," and much lower at the younger ages than among cases not admitted to the hospitals of the Board.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6741 births and 4729 deaths were registered during the week ending March 3rd. The annual rate of mortality in these towns, which had been 25·8 and 24·2 per 1000 in the two preceding weeks, further declined last week to 21·2. In London the rate was 19·0 per 1000, while it averaged 22·7 in the 32 provincial towns. The lowest death-rates in these towns were 14·8 in Gateshead, 15·9 in West Ham and in Croydon, 16·8 in Nottingham, and 17·2 in Brighton; the highest rates were 29·8 in Preston, 30·1 in Plymouth, 30·7 in Salford, and 31·2 in Liverpool and in Blackburn. The 4729 deaths in these towns included 416 which were referred to the principal zymotic diseases, against 469 and 444 in the two preceding weeks; of these 121 resulted from whooping-cough, 115 from measles, 75 from diphtheria, 40 from "fever" (principally enteric), 32 from scarlet fever, 32 from diarrhœa, and 1 from small-pox. No fatal case of any of these diseases occurred last week in Croydon, Swansea, Birkenhead, or Gateshead; in the other towns they caused the lowest death-rates in Plymouth, Nottingham, Derby, and Hull, and the highest rates in Wolverhampton, Salford, Oldham, Blackburn, and Preston. The greatest mortality from measles occurred in Bristol, Wolverhampton, Blackburn, Preston, and Sunderland; from scarlet fever in Burnley; and from whooping-cough in Birmingham, Norwich, Salford, and Blackburn. The mortality from "fever" showed no marked excess in any of the large towns. The 75 deaths from diphtheria included 26 in London, nine in Sheffield, six in Leicester, six in Leeds, five in Portsmouth, four in West Ham, and four in Liverpool. One fatal case of small-pox was registered last week in London, but not one in any other of the 33 large towns. There were seven cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday last, March 3rd, against 17, eight, and 11 in the three preceding weeks; two new cases were admitted during the week, against one, none, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1872, against numbers decreasing from 3578 to 2009 on the 15 preceding Saturdays; 154 new cases were admitted during the week, against 157, 159, and 160 in the three preceding weeks. Influenza was certified as the primary cause of 42 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had been 527 and 485 in the two preceding weeks, further declined last week to 380, and were 188 below the corrected average. The causes of 74, or 1·6 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bolton, Oldham, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, Manchester, and Sheffield.

---

[2] See Report of the Medical Officer of Health of the County of London for 1894, p. 43.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 23·0 to 31·7 per 1000 in the seven preceding weeks, declined again to 29·0 during the week ending March 3rd, but exceeded by 7·8 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 16·6 in Leith and 21·2 in Aberdeen to 30·4 in Perth and 34·2 in Glasgow. The 897 deaths in these towns included 20 which were referred to measles, 18 to diarrhœa, 15 to whooping-cough, 10 to scarlet fever, six to "fever," and five to diphtheria. In all 74 deaths resulted from these principal zymotic diseases, against 82 and 69 in the two preceding weeks. These 74 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 24 and 17 in the two preceding weeks, rose again to 20 last week, and included 10 in Glasgow, four in Dundee, and four in Paisley. The deaths from diarrhœa, which had been 20 and 19 in the two preceding weeks, further declined last week to 18, of which eight occurred in Glasgow, three in Edinburgh, and three in Dundee. The fatal cases of whooping-cough, which had been 18 and 17 in the two preceding weeks, further decreased to 16 last week, and included six in Glasgow, three in Aberdeen, two in Edinburgh, and two in Paisley. The deaths from scarlet fever, which had been 11 and nine in the two preceding weeks, rose again last week to 10, of which nine were registered in Glasgow. The fatal cases of "fever," which had been two in each of the two preceding weeks, increased to six last week, and included four in Glasgow. The five deaths from diphtheria, of which four were recorded in Glasgow, corresponded with the number in the preceding week. The deaths referred to diseases of the respiratory organs in these towns, which had increased from 172 to 362 in the five preceding weeks, declined again to 324 last week, but were 111 above the number in the corresponding period of last year. The causes of 50, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·7, 42·4, and 51·0 per 1000 in the three preceding weeks, declined again to 34·3 during the week ending March 3rd. During the past four weeks the death-rate in the city has averaged 39·4 per 1000, the rate during the same period being 21·0 in London and 25·5 in Edinburgh. The 230 deaths registered in Dublin during the week under notice were 112 less than the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against 17, 15, and 11 in the three preceding weeks; of these five resulted from diarrhœa, four from "fever," one from measles, one from scarlet fever, and one from diphtheria. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 1·6 in London and 1·2 in Edinburgh. The fatal cases of diarrhœa, which had been two and four in the two preceding weeks, further rose to five last week. The deaths referred to different forms of "fever," which had been three and one in the two preceding weeks, increased again last week to four. The mortality from measles showed a marked decline from that recorded in the preceding week. The 230 deaths registered in Dublin last week included 35 of infants under one year of age and 69 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a considerable decrease from the numbers in the preceding week. Four inquest cases and two deaths from violence were registered, and 84, or more than a third, of the deaths occurred in public institutions. The causes of 10, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following qualified candidates for the Royal Navy Medical Service have been appointed to be Surgeons in Her Majesty's Fleet:—Herawald Evelyn Croker Fox, James Garfit Wallis, William Percival Walker, Robert William Glennan Stewart, John O'Hea, Robert Robertson Fasson, John Reid Muir, Leonard Sykes Whitwam, Arthur Forbes Fraser, Arthur Stanley Frank, Herbert Reginald Harry Denny, Ralph Bignell Ainsworth, John St. John Murphy, Alfred James Hewitt, Gerald Meade Eastment, Henry Ivers Rogers, Alexander Cameron Renwick, Walter Percy Dyer, Thomas Hedley Vickers, and Richard Rothwell Horley.

Surgeon Ernest Albert Shaw has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

The following appointments are notified:—Staff Surgeons: R. W. Anderson to the *Caledonia*; J. H. Stenhouse for medical charge of the *Edgar* on voyage home. Surgeons; J. W. W. Stanton, for medical charge of the *Edgar* on voyage to China; F. T. Sutcliffe to the *Boscawen* for the *Seaflower*; R. Hughes to the *St. Vincent* for the *Martin*; E. O. B. Carbery to the *Boscawen* for the *Dolphin*; G. E. Glynn to the *Boscawen* for the *Wanderer*; J. K. Raymond to the *Impregnable* for the *Nautilus*; G. M. O. Richards to the *Impregnable* for the *Pilot*, A. J. Laurie to the *Lion* for the *Liberty*; J. H. Jones to the *Sharpshooter*; F. Bradshaw to the *Bellona*; J. C. Ferguson to the *Wallaroo*; F. Bolster to the *Rosario*; T. E. Honey to the *Basilisk*; and E. Haines to the *Humber*.

THE IMPERIAL YEOMANRY.

Surgeon-Captain J. Wreford, 1st Northumberland Volunteer Artillery, is granted the temporary rank of Captain whilst serving with the Volunteer Battery in South Africa. To be Medical Officers, with the temporary rank of Captain: Emelias Hopkinson and Hay Reynolds.

COLONEL LUMSDEN'S CORPS.

Surgeon-Captain Samuel A. Powell, Surma Valley Light Horse Volunteers, to be Medical Officer, with the temporary rank of Captain; William Stevenson to be Veterinary Officer, with the temporary rank of Lieutenant.

Lord Strathcona's Corps.

Campbell B. Keenan to be Medical Officer, with the temporary rank of Captain.

Royal Army Medical Corps.

The undermentioned Surgeon-Lieutenants of the Volunteer Medical Staff Corps are granted the temporary rank of Lieutenant whilst serving in South Africa:—John William Smith, and Edmund William Herrington.

The following officers are detailed for duty with No. 9 General Hospital:—Majors A. Hosie and M. T. Yarr, and Captain F. Smith, R.A.M C., and Surgeon-Lieutenants J. W. Smith and E. W Herrington, Volunteer Medical Staff Corps.

Colonel C. A. Maunsell, Administrative Medical Officer in Bombay, is appointed Principal Medical Officer of the South-Eastern District in place of Colonel H. Comerford who relieves Colonel Maunsell at Bombay.

India and the Indian Medical Services.

The Queen has approved of the following appointments to Her Majesty's Indian Medical Service:—To be Surgeon-Lieutenants (dated Jan. 27th, 1900): Archibald Currie MacGilchrist, John Wallace Dick Megaw, Edward Owen Thurston, George Browse, Cecil Maurice Goodbody, Robert Steen, Frederick Fenn Elwes, Ian Lamont MacInnes, Ernest Albert Churchward Matthews, Lessel Philip Stephen, Leonard Gilbert, Thomas George Nesbitt Stokes, Harry Malcolm Mackenzie, Michael Harris Thornely, Francis Victor Owen Beit, William O'Sullivan Murphy, Matthew Corry, Cecil Charles Murison, Herbert Armstrong Williams, William Christopher Long, and George Crofts Beamish.—*London Gazette.*

Army Medical Reserve of Officers.

Surgeon-Captain John Arnallt Jones, 2nd Volunteer Battalion the Welsh Regiment, to be Surgeon-Major.

Militia.

Infantry: 4th Battalion the Lincolnshire Regiment: Surgeon-Lieutenant-Colonel G. W. Shipman, Militia Medical Staff, resigns his commission, with permission to retain his rank and to wear the prescribed uniform on his retirement.

Yeomanry Cavalry.

Suffolk (the Duke of York's Own Loyal Suffolk Hussars): Surgeon-Major A. Cooper to be Surgeon-Lieutenant-Colonel.

Volunteer Corps.

Royal Engineers (Volunteers): 1st Devonshire and Somersetshire: Arthur Stanley Wohlman to be Surgeon-Lieutenant. *Rifle:* 1st Roxburgh and Selkirk (the Border): William Hall Calvert to be Surgeon-Lieutenant. 4th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Captain G. McIntyre resigns his commission. 2nd Volunteer Battalion the Royal Sussex Regiment: George Reuben Robins Paine to be Surgeon-Lieutenant. 5th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): Lieutenant E. L Paton to be Surgeon-Captain. 1st Tower Hamlets: Surgeon-Captain W. D. Waterhouse, to be Surgeon-Major.

Transvaal War Notes.

The Government has sent a communication to each of the Universities of Glasgow, Edinburgh, St. Andrews, and Aberdeen asking for medical student volunteers.

The fund for the Welsh Field Hospital has been augmented by the sum of £150, the proceeds of a banquet and special appeal by Mr. Lloyd George, M P.

Lieutenant-Colonel W. A. May, R.A.M.C., of the Eighth Division, will leave Southampton for South Africa to day (Saturday).

We have received the plans of the Building Trades' magnificent gift to the nation, which takes the form of homes of rest and convalescent homes for discharged soldiers. These will be erected at Bisley at a cost to the Building Trades of £25,000.

The staffs of the Imperial Yeomanry Field Hospital and Bearer Company will be composed as follows.—*Field Hospital.*—Chief Surgeon and Military Commandant: Major C. Stonham, Senior Surgeon to Westminster Hospital. Surgeon: Mr. T. H. Openshaw, Surgeon to the London Hospital. Assistant Surgeons: Mr. A. W. Sheen, Assistant Surgeon to the Cardiff Infirmary, and Mr. A. H. Evans, Surgeon to the East Dispensary, Liverpool. Physician and Anæsthetist: Dr. J Purves Stewart, Assistant Physician to Westminster Hospital. Dressers: Dr. C. H. Jefferys, St. George's Hospital; and Mr. E. O. Carlin, Mr. S. W. Crowther, Mr. C. H. M. Hughes, Mr. C. A. Gill, Mr. G. J. Marett, and Mr. W. C. Nimmo, all of Westminster Hospital. *Bearer Company.*—Major G. E. Hale, R.A.M.C., D S O. Assistant Surgeons: Mr. A. A. Scot Skirving, Surgeon to Leith Infirmary, and Dr. Frederick Green. An inspection will take place on Monday at Devonshire House by the Prince of Wales and the hospital staff will probably sail about Tuesday in the steamship *Winkfield*.

Surgeon Captain Steele, Militia Medical Staff, has been ordered from Netley to Aldershot preparatory to his proceeding to South Africa.

The *Nile* transport arrived at Southampton on Monday, March 5th, with two officers and 40 men from the scene of war in South Africa. One of the men, O'Leary by name, of the West Surrey Regiment, was wounded by a Mauser bullet at Colenso. The ball was removed from the brain under the supervision of Sir William Mac Cormac at Maritzburg Hospital. All the men had served under Sir Redvers Buller in the attempt to cross the Tugela on Dec. 15th, 1899. The invalids were admitted to the Royal Victoria Hospital, Netley, during the morning. On the same day the Cunard steamer *Aurania* arrived at Southampton from South Africa. She carried 174 wounded invalids, but arrived so late in the day that the men were not admitted to Netley Hospital until 9.30 in the evening.

The s.s. *Dunera* arrived in port on March 4th. She carried 28 invalids who were sent on to Netley. The transport *Britannic* from the Cape also arrived at Southampton on March 4th, having on board three officers and 40 men invalided from the seat of war. Most of the wounded had been engaged with Lord Methuen's column at Magersfontein and Modder river and had passed through the Wynberg Hospital. Many of the wounded had lost limbs. They were sent on to Netley by special train.

We hear that 32 additional Dœcker huts are being erected in the rear of the Royal Victoria Hospital, Netley, also 40 iron huts and the necessary cook-houses and offices. The 102 huts are to be used for convalescents and will accommodate over 1000 men.

Messrs. Offord and Sons of Gloucester-road and Fulham-road, S.W., have presented the Imperial Yeomanry Loyal Suffolk Hussars with a two-wheeled ambulance vehicle, light in construction, but strong and well suited for rapid transit. Two removeable stretchers are placed on the floor of the vehicle, and at a short distance above them there is a frame carrying two other similar stretchers. These four stretchers with sick or wounded men can be lifted in or out at the back with the utmost readiness, the vehicle being steadied, if necessary, during the process by temporary iron props fixed to the back and front of the body and resting on the ground. There is an ingenious arrangement by which the frame for holding the upper two stretchers can, when not required for that purpose, be at once converted into seats. Particular attention has been paid to the springs supporting the body. The vehicle is covered with canvas stretched over an iron frame which can be taken to pieces. It is provided both with shafts for one horse and with a pole for two. A basket to hold medical and surgical requisites is slung underneath with straps. The wheels are about four feet in height.

The authorities of the German Hospital at Dalston have placed 10 beds at the disposal of the War Office for the use of soldiers invalided from South Africa.

Five railway ambulance carriages are being built for the medical department of the War Office by the London and South-Western Railway Company and are expected to be completed within a week or two. Each carriage will be 48 ft. long and 8 ft. wide and will be carried on steel bogies of the latest improved pattern. The interior arrangements will consist of a central compartment 31 ft. 3 in. long in which there will be 12 spring beds and seating accommodation for the less serious cases. At each side of the carriage there will be double doorways to allow of the spring beds being carried in and out. The end compartments will be one for the medical or invalid officers and the other for patients, each having a lavatory adjoining. Each carriage will be provided with a gas-stove for warming food, together with other necessary accessories, and there will be gangways connecting the carriages to enable the medical staff to pass from one vehicle to another.

The Gamle Carlsberg Breweries Alliance, Copenhagen, has given to the hospital ship *Princess of Wales* 200 dozen of their specially brewed imperial stout.

The secretary of the Central British Red Cross Committee writes to say that the statement which has appeared in several papers to the effect that the Dœcker huts recently erected at Netley were lent by the German Red Cross Society is not true. Through the kindness of the Central Committee of the German Red Cross Societies the Central British Committee was able to obtain within a very short time a large number of huts which the manufacturers had been making to the order of the German Central Committee, but the huts have been purchased, not obtained on loan."

THE ARMY ESTIMATES.

According to the army estimates for the financial year which commences on April 1st and ends on March 31st, 1901, the total number of men for which provision is made is 430,000, as compared with 184,853 in the estimates of 1899-1900, a net increase of 245,147. The expenditure for the coming year is put down at £61,499,400, as against £20,617,200 in the estimates for the 12 months now drawing to a close, an increase of £40,882,200. In addition, there was this year a supplementary estimate of £10,000,000 and 35,000 men passed by the House of Commons in October, and the supplementary estimate for £13,000,000 and 120,000 men agreed to last month. Among the separate items in the estimates is one for £555,000 for pay, &c., of the medical establishment. In Lord Lansdowne's remarks dealing with the increases in the various votes the War Minister says: "The medical vote has been nearly doubled owing to the war. All the available officers of the Royal Army Medical Corps ordinarily on the home establishment have been sent to South Africa, and their places at home have been filled by the employment of retired officers and civil medical practitioners. In addition a large number (223) of civil surgeons have been sent to the seat of war. The services of seven surgeons of eminence have been accepted as 'consulting surgeons' to the army in the field. The Army Nursing Reserve, which was constituted in 1897, has been largely drawn upon to supplement the Army Nursing Service in the field and at home, and the services of members of the St. John Ambulance Brigade have been largely utilised. Provision has been made for a large increase of officers of the Royal Army Medical Corps, and a further addition has been made to the establishment of non-commissioned officers and men." As at present arranged the Army Estimates will not be taken later, at all events, than Monday next. But for the indisposition of Mr. Wyndham it would have been definitely arranged to take them on Thursday or Friday.

ARMY MEDICAL SCHOOL, EIGHTIETH SESSION, 1900.

The following is a list of nominated surgeons on probation, Royal Army Medical Corps:—

Names.	Qualifications.	Studied at
A. F. Weston ..	L.S A. Lond.	St. George's Hosp., Lond.
P. G. Stock	M.R.C S Eng L.R.C P. Lond	Bristol.
J. M. Cuthbert ...	M.B, Ch B Edin	Edinburgh.
F. MacLennan ...	M B, Ch B Aberd.	Aberdeen.
J. Dorgan	M.B, B Ch. R U.I.	Queen's College, Cork.

DEFECTIVE SANITATION IN THE ITALIAN NAVY.

In the *Rivista Marittima* for October, 1899, Dr. Belli of the Italian navy draws attention in a very outspoken article to the defective sanitation of the fleet. On board the Italian men-of-war, he says, ordinary comfort is sacrificed to ridiculous ornamentation, while æsthetic adornment takes the place of wholesome cleanliness. Descending to particulars the writer continues his attack *seriatim*: 1. The ventilation is almost inoperative, not having been thought of until after the hulls had been partitioned off. The ventilators are distributed in a haphazard fashion; and apparently a large cabin is considered to be thoroughly provided for when a single minute inlet has been inserted. 2. The water-supply, derived from distillation, is barely sufficient for drinking purposes and is totally inadequate for ablution. 3. The kitchens, storerooms, &c., are all dark, stuffy, and impossible to keep clean. 4. The latrines, which are on the Turkish system, are indescribable; there are no lavatories except in a few ships where they exist for the stokers alone, and the officers' baths are so ill-fitted that they are never used. 5. There are no "cold rooms" for preserving meat and putrescible food. 6. The appliances for washing clothes are most inadequate, boiling being for the most part the only detergent method possible. 7. The sick bays and dispensaries are all insufficient and old fashioned; few ships are provided with disinfecting apparatus. In conclusion Dr. Belli gives a highly laudatory account of the United States Museum of Naval Hygiene, having had the opportunity of inspecting that institution when he visited New York in 1897 in the *Colombo*, of which vessel he was surgeon-major.

MARCHES AND SOLDIERS' EQUIPMENT IN SOUTH AFRICA.

It has been found as a matter of experience in South Africa, as well as upon many other occasions in previous expeditions, that marching troops for long distances in the heat of the day is attended with a good deal of falling out from heat exhaustion and sunstroke, especially where an abundant supply of water is not available, as sometimes must be the case. A special correspondent of the *Standard* calls attention to the experience of the troops in these respects on the occasion of the march on Feb. 3rd of General Macdonald's Highland Brigade, and dwells upon the unsuitability of the equipment of the men for a campaign in South Africa, with the addition of a weight of 150 rounds of ammunition. He alludes also to the unsuitability of the kilt for the marches and exceptional kind of field service in South Africa, with its difficult rocky ground and stretches of country covered with a kind of sharp thorn scrub. It would, no doubt, be better to have all the troops clad in khaki and to reserve the kilt for other occasions. During the future operations attempts will probably be made, as far as practicable, to hug rivers and streams in the marches and to take every advantage of lines of rail—on the route to Pretoria, for example. But it is scarcely necessary to point out that troops must go where they are required and that however desirable it is to carry their kits for them it frequently cannot be done.

DEATHS IN THE SERVICES.

Surgeon Benjamin Grant Heather, R N, at the Royal Navy Hospital, Stonehouse, on March 2nd, in his thirty-first year. Mr. Heather received his medical education at St. Thomas's Hospital, London, and qualified L.R C P. Lond. and M.R.C.S. Eng., in 1893. The deceased officer had held the rank of surgeon in the Royal Navy since May 16th, 1894. His last appointment was on the battleship *Magnificent*.

Inspector-General of Army Hospitals Thomas Guy, M.D. Heidelb., F.R C.P. Lond., at his residence, Dover, in his eighty-first year, on March 3rd.

Captain Alan Jasper Heath, I.M S., recently, at Exminster, aged 34 years. Captain Heath was the son of Mr. Christopher Heath, F.R C S. Eng.

ROYAL NAVY MEDICAL SERVICE EXAMINATION.

The under-mentioned gentlemen who competed on Feb. 19th, 1900, and following days at Examination Hall, Victoria-embankment, for appointments as surgeons in the Royal Navy have been granted commissions:—

Name.	*Marks*	*Name.*	*Marks.*
H E C Fox, M B	2436	H. R. H. Denny	2028
J. G. Wallis, M B	2334	R. B Ainsworth ...	2020

A. S. Frank, M B	2041	R. R. Horley	1717

Lieutenant-Colonel J. Lewtas, M.D. Lond, I.M.S, second surgeon to the Calcutta Hospital, who is at present at home on furlough, has been asked to serve at the Royal Victoria Hospital owing to the emergency created by the war in South Africa. Colonel Lewtas joined at Netley on March 2nd and is posted to the medical division for duty.

The services of Sir Thomas Fitz-Gerald, F.R.C.S. Irel., senior surgeon to the Melbourne Hospital, have been accepted by the British Government for South Africa.

Correspondence.

"Audi alteram partem."

"BORIC ACID IN FOOD."

To the Editors of THE LANCET.

SIRS,—Dr. M. K. Robinson in his letter to THE LANCET of Jan. 13th, 1900, p. 131, quotes against me a reference, made by me to Dr. Annett's investigations, that "all that these experiments really prove is already known—viz., that animals finally succumb under the repetition of large doses." He says: "This admission utterly destroys the value of Dr. Liebreich's experiment for the purpose of argumentative disproof of the toxic effect of boric acid in the case I narrated." But what I said referred only to Dr. Annett's experiments on kittens, which were given extraordinarily large doses of boric acid during a long period of time, whereas in the cases cited by Dr. Robinson the fowls were only given one large dose. And this dose cannot have been large enough to produce any ill-effects, because in that case the blancmange would have been uneatable on account of its strong taste. It is thus inadmissible to quote my reference to Dr. Annett's experiments as applicable to those of Dr. Robinson. Dr. Robinson further seeks to defend his contention that the case was one of boric acid poisoning by pointing out that the fowls died which ate the most blancmange and that those which took least recovered; and, further, says that the symptoms were very typical of poisoning by large doses of boric acid and that large quantities of boric acid were found, on the one hand, in the milk from which the blancmange was made and, on the other hand, in the crop and stomach of the dead fowls.

It cannot be regarded as in any way typical of boric acid poisoning that the fowls died which ate most of a poisonous blancmange while those which took least recovered. As regards the symptoms exhibited by his patients, which Dr. Robinson regards as characteristic of acute poisoning by boric acid, we have no knowledge of any typical symptoms of such poisoning. Nor can we form a judgment merely from symptoms, for many poisonous substances produce the same symptoms, including *suppressio urinæ*. It is natural enough that boric acid should be found in the crop and stomach of fowls which have eaten large quantities of a substance containing boric acid, and does not prove that the boric acid was the cause of their death. Such a conclusion would only be justified if the poisonous properties of boric acid in the quantities under consideration had been proved by experience of its effects upon human beings and experiments on animals. But as regards our experience of the effects upon human beings there exists no evidence for its poisonous nature. On the contrary, it has been proved, as already stated by me, "that excessive doses administered by the mouth cause only passing harm in man." Dr. Robinson would have acted more correctly if he had quoted this sentence instead of the one he did. Further, it would have been well if he had made careful experiments on animals. His experiments on the fowls only prove the poisonous nature of the blancmange and have no bearing on the question of the poisonous nature of boric acid. My own experiments on fowls conclusively show that boric acid does not poison them even when administered in doses as large as could possibly have been contained in the blancmange. The only conclusion warranted by them is that, in the case cited by Dr. Robinson, the poisonous effects were not produced by the boric acid, but by some other substance which must have been contained in the blancmange. Dr. Robinson has himself taken this hypothesis into consideration, but believes himself justified in rejecting it because a chemical analysis did not prove the presence of *tyrotoxicon*. But it is a principle universally accepted in toxicology that the negative result of a chemical analysis is not always conclusive of the absence of a poisonous substance, and this is especially true for the easily decomposable substances ptomaine and toxalbumin. Dr. Robinson also rejects the hypothesis of vanilla poisoning. Many toxicologists are now inclined to regard cases of vanilla poisoning as really due to tyrotoxin. But there are no conclusive proofs for this theory. Dr. Robinson says that he is unaware of any poisonous effects which have been traced to vanilla in a pure state. But what grounds has he for assuming that the vanilla employed by the cook in preparing the blancmange was "in a pure state"?

I do not for a moment attribute to Dr. Robinson any desire for sensational publicity; at the same time it cannot but create a sensation when poisonous properties are suddenly ascribed to a non-poisonous substance.

I am, Sirs, yours faithfully,

Berlin, March 5th, 1900. OSCAR LIEBREICH.

THE LUNACY ACT, 1900.

To the Editors of THE LANCET.

SIRS,—All interested in the public asylum service will much appreciate the sympathetic tone of the leading article in THE LANCET of March 3rd (p. 631) having reference to this year's Lunacy Bill. The omission from that Bill of any pension clause is to be deprecated not merely from the point of view of the asylum official but also from that of the public. In the interest of the amelioration and recovery of the insane the importance of securing and retaining the best class of officers, attendants, and nurses for public asylums is obvious, and to do this the prospect of an assured and sufficient retiring allowance for those who have spent their best days in this arduous and trying service is essential. The improvement of the status of attendants and nurses in asylums by encouraging them to avail themselves of opportunities of training and by enlisting a share of public interest on their behalf, together with the formation of a fund for mutual benevolent aid, was the main object of the formation in 1896 of the Association of Asylum Workers, which now comprises over 3000 members and is presided over by Sir James Crichton Browne. The preparation and presentation in 1898 of a petition to the Lord Chancellor on the subject of pensions was the work of this body and not of the Medico-Psychological Association of Great Britain and Ireland (as stated in the article above mentioned). The latter is the representative organisation of asylum medical officers throughout the country and of medical men interested in psychological medicine, whilst the Association of Asylum Workers is largely (but not exclusively) composed of the "rank and file" in asylum service. Both associations are, however, interested in the question of satisfactory superannuation and have worked from their respective standpoints in similar directions in trying to secure this object, so important on public as well as on private grounds.

I am, Sirs, yours faithfully,

G. E. SHUTTLEWORTH,
Honorary Secretary, Association of Asylum Workers.

Richmond, Surrey, March 6th, 1900.

"THE ANATOMY AND PATHOLOGY OF THE RARER FORMS OF HERNIA."

To the Editors of THE LANCET.

SIRS,—In connexion with the valuable lectures by Mr. Moynihan published in THE LANCET of Feb. 24th and March 3rd I may, perhaps with advantage, briefly record a case of reduction in mass of the third variety mentioned by him in the first lecture (Fig. 7 C., p. 518).

A woman, aged 65 years, was admitted into the Hampstead Workhouse infirmary on May 19th, 1899, suffering from abdominal pains and vomiting. This condition had been going on for four days and had been labeled gastritis, but when she was admitted the vomit was fæcal and there was a small irreducible swelling over the right femoral canal. After considerable difficulty she was persuaded to undergo an operation. Under A.C.E., taxis proving useless, the sac was opened and a knuckle of small intestine and some omentum were found strangulated but in a recoverable condition. I think by the slight diminution in size of the tumour during taxis that some fluid had been driven into the abdomen; there was practically none found on opening the sac. "The stricture at the neck of the sac" was very carefully divided, and while notching the sharp edge of Gimbernat's ligament of course the peritoneum was slightly cut. On applying pressure to the bowel it presently slipped back, but without the usual pleasant gurgle. On introducing the little finger the bowel seemed to lie in a free cavity, though there was a "string" felt that was curious; this really must have been the torn edge of the peritoneum. The operation was concluded without special feature. After the operation and through the night the patient seemed a little better, but the next afternoon she began vomiting fæcal matter again; the abdomen was swollen though soft and the pulse was not good. Unfortunately she absolutely refused any further operation. She died on the 24th, nearly five days after the operation.

At the post-mortem examination I found on opening the abdomen that the accident described by Mr. Moynihan had occurred. About four inches of small intestine were lying empty and flaccid between the peritoneum and the pubes. This was very easily drawn out and was in very fair condition, so that by an abdominal section I think it would have been quite easy to have completed the operation satisfactorily. Beyond some slight hyperæmia in the neighbourhood there was not any peritonitis.—I am, Sirs, yours faithfully,

E. CLAUDE TAYLOR, M.S. Lond., F.R.C.S. Eng.,
Medical Officer to the Hampstead Workhouse Infirmary.
March 5th, 1900.

To the Editors of THE LANCET.

SIRS,—In the last of Mr. Moynihan's Arris and Gale Lectures, published in THE LANCET of March 3rd, p. 597, he mentions that "four cases of inguinal cystocele have been recorded in children." To these allow me to add another case which came under the care of my friend, the late Mr. E. S. O'Grady, while he was surgeon to Mercer's Hospital in this city. The case was admitted to hospital in 1883, and in the session 1883–84 Mr. O'Grady read a paper on the subject before the surgical section of the Academy of Medicine in Ireland, the late Mr. Edward Hamilton being in the chair. As the case is an interesting one and as it does not appear in the Transactions of the Academy of Medicine I think the principal facts are worthy of being placed on record.

A boy, apparently six years old, was admitted to Mercer's Hospital under Mr. E. S. O'Grady's care suffering from a painful swelling in his left inguinal region. He stated that the swelling was there for more than a year and that he had never experienced any inconvenience from it, though latterly it had greatly increased in size. A few days before admission to hospital, when the swelling was at its largest, he had bruised it in a fall and from that time it was painful. The lump was of about the size of a small orange, rather painful to handle, and the boy drew attention to the fact that when he pressed the lump with his hands he made water. After a few days' rest in bed the pain disappeared and then Mr. O'Grady operated. On cutting on the lump he came upon a cystic tumour, uncovered by peritoneum, from which the fluid was readily expressed, with the result that urine flowed from the penis. The sac was now opened and the healthy mucous coat of the bladder came to view. A catheter was now passed through the urethra and its point was brought out through the incision. The bladder was sewn up and a radical operation performed and the boy left the hospital in a few weeks. The case resembles that of Mr. P. Pott as reported in Sir James Earle's edition of his monograph on Ruptures. It is a pity that our old classical medical writers are not more read. Neglect of them has caused us to overlook Pott's case of Mr. Nourse's patient from whom he successfully removed both ovaries before M'Dowell was out of his long clothes.

I am, Sirs, yours faithfully,
Dublin, March 5th, 1900. GEORGE FOY.

THE OBSTETRICAL SOCIETY OF LONDON AND THE MIDWIVES QUESTION: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I beg, through the columns of THE LANCET, to make an earnest appeal to each fellow of the above society. There is little doubt but that this society has been the prime mover in the agitation *re* midwives' registration. Although the society was established in 1858 it was not until 1872 that it entered upon the down-grade act of examining and granting documents to intending midwives. Since that time over £3966 worth of diplomas have been sold, while over £1957 have been handed to the few fellows who conduct the said questionable examinations. I think it was one of the saddest and most humiliating episodes in connexion with any body of practitioners when they formed themselves into a voluntary society and established a "back door entrance," so that certain persons could practise that branch of medicine known as midwifery and without undergoing the usual medical education and examination.

What will be done if other medical societies degrade themselves and their profession by following so evil an example? And can any practitioner—any honest practitioner—state that if one society takes it upon itself to grant certificates which profess to empower the holder to practise *midwifery* it is not equally open for any other society to grant a certificate empowering the holder to practise minor *medicine* or *surgery?* It is most regrettable that it has alone fallen to the lot of medical men to establish so debasing and dangerous a line of conduct. Do we hear of barristers or solicitors, or dentists, veterinary surgeons, or chemists, or any of their societies, beginning to sell diplomas to persons which profess to entitle the holders to practise minor law, dentistry, pharmacy, &c.? Thank God, they have not fallen so low. But unfortunately the degrading action of the above society has been imitated by a number of persons who took it on themselves to grant an "M.D. Bc." I refer to the "General Council of Safe Medicine, Limited," also the "National Association of Medical Herbalists"; its examining council is now competing on similar lines with the Obstetrical Society and is granting diplomas in medicine and midwifery. Now, Sirs, we all know that our legislature has appointed certain universities and colleges to examine and grant degrees and diplomas to those who wish lawfully to practise medicine, surgery, and midwifery. Unfortunately, the legislature thought that we were a body of honourable men and that every one of us would do our best to carry out the Medical Acts. Present actions show that our legislators did not know that there were a few traitors who would go behind these Acts. Had they known of this intrigue practically to repeal the Acts they would have inserted a section making it an offence if *any* persons other than those appointed by Act of Parliament granted any documents professing a power to practise.

In 1894 I petitioned the General Medical Council to make a rule to the effect that the Council will consider it "infamous conduct in a professional respect" if any practitioners other than those appointed by Parliament grant any document which professes to empower the holder to practise any branch or part of medicine, surgery, or midwifery. Mr. C. G. Wheelhouse gave the petition his powerful support (see Minutes, May, 1894). In 1895 I had a petition signed by over 40 members of the Obstetrical Society of London to the same effect as the above presented to the General Medical Council (see Minutes of the General Medical Council, May, 1895).

What I wish to propose now is that every fellow of the Obstetrical Society of London who feels that the society should cease forthwith to examine and grant documents to intending midwives shall write at once to the secretary of the society (20, Hanover-square, London, W.) stating that if the society does not cease to grant documents to intending midwives he will resign his connexion with the society. There are about 711 fellows of the society. If the majority of these resign, and, if they wish, become fellows of the British Gynæcological Society instead, they will for the same annual subscription (20*s.*) not lose anything. I shall be glad to hear from any of the society's fellows and, if they wish, to publish a list of protesters in the medical papers.

I am, Sirs, yours faithfully,
Liverpool, March 2nd, 1900. R. R. RENTOUL.

DEATHS UNDER CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—I am constrained to ask space to comment on a case of death under chloroform reported in THE LANCET of Dec. 30th, 1899, p. 1811, with remarks by Dr. Mowat, the chief point to which I wish to call attention being his initial remark that "the patient undoubtedly died from syncope." It is true that when respiration begins to fail the heart's beat rapidly weakens, but this is not primary heart failure, nor does such a patient die from syncope. It will be admitted that the criterion as to whether a man dies from syncope or paralysis of the respiratory centre is the determining whether heart or respiration fails first. Unfortunately, in the case under consideration this essential piece of information is omitted, so that it is impossible to draw any definite conclusion as to the cause of death. The information actually given on this point is that "the patient continued to breathe for a short time after his head was lowered," which was done immediately on the onset of dangerous symptoms, and that "auscultation failed to detect any heart-beat ten minutes after the appearance of dangerous symptoms." If these expressions warrant any guess (it cannot even be an opinion) as to whether heart or breathing failed first they point to primary respiratory failure. If a published case is to be of *any use it must be fully reported so that all who read* may form their own conclusions. In no other way can the vexed question of the mode of death under chloroform be finally settled, for no man can be expected to accept unhesitatingly another man's dictum on a questionable point. In this case I think I may claim to have shown that there is no proof that the death occurred from heart failure, but that the presumption on the imperfect facts published is that death resulted from respiratory failure. As already hinted, however, the principle at stake here is, if such is possible, even more important than the determination of the mode of death in any particular case—namely, the absolute necessity for the full and candid report of all cases of death under chloroform as an essential preliminary to the accurate determination of the mode of death in such cases. In nearly every such case reported in THE LANCET the writer expresses his opinion that death occurred from syncope, and yet a perusal of his report, lacking in detail though this almost invariably is, shows that death almost certainly occurred from respiratory failure. Unless a report is full and accurate it may just as well not be written, so far as it provides a decisive addition to our knowledge in this direction, while an accumulation of accurate clinical detail will go far towards settling this disputed point, and this determination cannot but be followed by far-reaching beneficial results. I am, Sirs, yours faithfully,

CLAYTON LANE, M.D. Lond., Lieutenant, I.M.S.

Camp Grimbum, Bebejiya, Mishmi Field Force,
Jan 28th, 1900.

"THE PHYSIQUE OF THE BOERS."

To the Editors of THE LANCET.

SIRS,—As inquiries prompted by my letter in THE LANCET of Feb. 24th, p. 574, continue to reach me please allow me to state in your columns that the title of Mr. E. Howard's book is "*To-morrow*," that it is published by Swan Sonnenschein at 2*s*. 6*d*., and that the honorary secretary of the Garden City Association is Mr. C. M. Bailhache, 3, Elm-court, Temple, E.C., from whom all information may be obtained. I am, Sirs, yours faithfully,

Belsize-road, N.W., March 5th, 1900. W. WINSLOW HALL.

THE POSITION OF THE RETIRED ARMY MEDICAL OFFICER.

To the Editors of THE LANCET.

SIRS,—I would most respectfully request to publish through your influential journal the following question:—Are officers who retired from the Royal Army Medical Corps, but who are now once more doing *duty on full pay* with troops, to count their *present service towards pension?* For if not a great hardship—not to say an act of injustice—is being done to them. To quote a true case in point:—A major retired on a gratuity after 18 years' service. Six weeks before his name appeared in the *Gazette* he asked to be allowed to withdraw his resignation, but the War Office authorities refused his application, probably thinking that young medical men were about to flock into the Army Medical Service and that therefore this gentleman might easily be spared and his pension saved. A year or so afterwards, however, being very short-handed for medical officers, they were only too pleased to avail themselves of his services and placed him once more on full pay and gave him a full share of army medical work. *Is this duty to count for nothing even towards pension*, for the questions of promotion or of restoration to the active list can be left out of consideration for the present?

I am, Sirs, yours faithfully,

March 5th, 1900. RETIRED ON GRATUITY.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Sewerage Trouble in Bombay: the New Scheme.—The Terrible Mortality in Bombay.—Further Spread of the Plague in India.—Increase of the Disease in Calcutta.—The Impotence of the Government.

THE city of Bombay has been troubled about its sewerage for many years. Part of it is under the Shone system, a part of the city is not sewered at all, but the greater portion has its sewage pumped out to sea on the western side of the island. Here it is that a nuisance is complained of. At certain states of the tide the sewage is seen to travel slowly southwards past the residential districts of Cumballa and Malabar Hills and it gives off most offensive odours. In order to remedy this state of things and to provide for the sewerage of the northern portions of the city the municipality sought the advice of Mr. W. Santo Crimp and he has just issued his report. From this it appears that the greater part of the city is drained into a place called Lovegrove, where four modern and powerful engines pump the sewage out to sea on the western side of the island six feet below the lowest spring-tide. Each engine is capable of pumping 15,000,000 gallons a day, but three engines only are kept working at the same time. The regular working capacity of the two sewers carrying the sewage from the pumps is put at 37 27 million gallons in the 24 hours, but for the year ending March, 1899, the daily average was 30 4 million gallons. This is estimated at 4,500,000 gallons less than the water-supply of the city, the balance of the water supplied going for road-watering, garden-watering, and the unsewered portions of the island. The sewage reaching the pumping station is said to be rather stronger than London sewage, and this is partly explained by the immense quantity of cattle kept in Bombay. The sewage having been pumped out to sea rises to the surface and spreads itself upon the sea water. When the tide turns the sewage is deflected towards the south and forms a distinct stream reaching Malabar Point at about low water. It is where this stream is passing south that the smells are complained of. Mr. Santo Crimp then discusses various remedies. He puts aside diversion of the sewage to Colaba or Malabar Points as too expensive. The use of electrolysed sea water is also put out of further consideration on account of the great cost of the necessary plant. It having been suggested that an additional outfall from the foreshore into deeper water might be made he points out that as the ebb tide sets towards the south more sewage and larger works would only increase the evil. Moreover, if further areas of the city were drained into this direction the outfall sewers would have to be enlarged. With reference to this outfall he suggests, therefore, that crude manganate of potash and sulphuric acid should be added to the sewage. It would not be necessary to employ it at all hours of the day but only to that volume of sewage which flows south at the turn of the tide. For the new scheme of drainage for the northern and north central portions of the city he suggests that the sewage should be discharged at Worlee Point. This is to be carried well out to sea and to be discharged only upon the first four hours of the ebb tide. The sewage would then not prove obnoxious. For the disposal of the sewage for the whole of Bombay when the works are all completed he suggests that for certain hours—viz., from the turn of the tide at high water to four hours after—all the sewage of the city should be discharged from Worlee Point. After this time it should be diverted to the present outfall at Lovegrove. It could then continue to be discharged until high water again when it might once more be diverted to Worlee. Thus one-third of the sewage of the city would be discharged at Worlee and the remainder at Lovegrove.

The Bombay Presidency is a most unfortunate one. Constantly afflicted with the plague during the past three and a half years it is now the seat of the greatest distress from famine. The two cities of Bombay and Poona have become famous for the most intense forms of plague Poona surpassed all previous records by its terrible mortality last August and now Bombay returns the highest death rate it has ever known For a city the average weekly mortality of which is 500 it will be seen that the 2637 deaths which occurred last week are a terrible record This is a rate of over 167 per 1000 per annum Of this great mortality probably 250 deaths occurred from small pox Ordinary diseases, especially those of the respiratory system, are said to be unusually prevalent, colds and coughs troubling nearly everyone It will not probably be far wrong to estimate the past week's mortality from plague at 1600, although the official returns only give 569. It is said that numerous cases occur in which both plague and small pox have attacked the same person, the condition of the patient being then pitiable in the extreme

For the whole of India the deaths from plague rose from 1869 to 2137 In Bengal the disease is fast spreading, and a fresh outbreak is developing in Calcutta Patna recorded no less than 675 deaths and for the city of Calcutta there were 106 deaths Since the returns were published the disease has still further increased in Calcutta and there are now from 25 to 30 deaths occurring daily An increase of plague is also reported from the Punjab, within the Jullunder district

In view of this increase of plague in several parts of India it is interesting to recall the great powers possessed by local governments through the Epidemic Diseases Act of 1897, but which, admittedly of the greatest value if properly enforced, cannot be carried out in India The attempt to do so has miserably failed everywhere and has led to a most lamentable spirit of antagonism Dissatisfaction sedition, and panic have invariably followed By slow degrees the enforcement of the harsher regulations has been dropped and even the milder measures are only imperfectly carried out At the present moment the only machinery really existing is that which the Venice Convention insists upon The consequence is that it is impossible to say how many deaths from the epidemic are now taking place The Government apparently can do nothing All depends upon the action of the people and their native leaders

Feb 15th

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Women Students and the Manchester Royal Infirmary.

AT the meeting of the Board of Management of the Manchester Royal Infirmary held on Feb 26th, a letter was received from Dr Hopkinson Principal of Owens College, acknowledging the receipt of a communication from the House Committee as to the admission of women students from the College to the hospital practice at the infirmary on the same terms as men except to the surgical out-patient department In it he said the Council of the College were glad to know "that such students will now by the joint action of the College and of the Royal Infirmary be able to obtain satisfactory qualifications for the medical profession in Manchester' 50 years ago such a step as this would have been considered absolutely shocking, now it comes as a matter of course Sir J W Maclure, Bart, M P, said he had the greatest confidence that the new arrangement would be beneficial to society and to the infirmary itself, but he thought it a very prudent course that the exception had been made as to the out patients

Inspection of Food in Manchester

The enormous waste of food constantly going on is not very often brought to mind, but the report of the Markets Committee to be presented to the City Council gives some impressive figures In 1899 under the head of "meat and fish" 177 822 lb were condemned and destroyed and of "fish' 147,996 lb 11 307 head of game rabbits, poultry, &c, were confiscated besides a large quantity of small fruits The same thing is no doubt going on in every town, large and small from London downwards throughout the whole country The money loss must be very great and the utilisation of all this food would cheapen existence There is evidently plenty of scope for the discovery and use of innocuous methods of food preservation

Ladies Sanitary Work

Among the more interesting examples of work in aid of the prevention of disease in Manchester is that of the Ladies' Health Society and the Ladies' Society for Visiting the Jewish Poor, which is carried out under the sanction and direction of the medical officer of health It is a good illustration of the coöperation of voluntary philanthropic effort with that of the constituted authorities The former of the two societies deals with a larger population and a wider area than the latter, for though the number of poor Jews in Manchester is considerable they chiefly live, as is their custom, in what is truly the Jewish quarter of Red Bank and Strangeways The health visitors have made 8631 inspections of houses in the course of a systematic house to house visitation during the last quarter. When met with dilapidation of the houses, dirt, overcrowding, and sickness are reported to the health office It is remarkable how much variation there is in adjoining districts Four per cent of the houses were dilapidated, but in one district, that of West Hulme, the proportion rose to 24 per cent 12 per cent of the houses were dirty, but in East Hulme the proportion was 38 per cent, while in Central Hulme only 0 1 per cent was reported as being dirty Birds of a feather still bear out the adage and continue to flock together It is curious that while in the Jewish quarter of Red Bank 9 per cent only of the houses had sick inmates, in the Gentile district of West Ancoats the percentage of houses with cases of sickness was no less than 44 It can scarcely be assumed that the cleanliness of the Jews in Red Bank greatly outshone that of the dwellers in Ancoats—though both might be improved—and the explanation must be sought probably in their religious ceremonial customs and possibly in their racial peculiarities Temperance in the use of alcohol will no doubt be found more frequently in Red Bank than in Ancoats The health visitors distributed no fewer than 8471 leaflets on (1) the prevention of diarrhœa; (2) the prevention of consumption, (3) precautions against measles, (4) precautions against whooping cough, (5) suggestions to householders, and (6) how infants should be fed A supply of disinfecting powder was left at 8028 houses, several hundredweight of soap were sold—no doubt at a cheap rate—dry lime and brushes were given, and during the quarter the tenants were induced to cleanse and whitewash 2029 rooms, closets, yards, and the like 102 neglected children were found and looked after, while 993 families were helped in various ways, such as in regard to the care and treatment of children and as to food and clothing This work is so good that the only regret is that it merely touches the surface of the mass of ignorance, idleness vice and poverty that lies festering in our midst More help is needed both in workers and in means before this mass can be inter penetrated and leavened into wholesome life

March 6th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Royal Edinburgh Asylum

THE statutory annual meeting of the corporation of the Royal Edinburgh Asylum for the Insane was held on Feb 27th, the Lord Provost of Edinburgh presiding The managers report for the year 1899 stated that the ordinary revenue amounted to £54 993 2*s* 6*d* and the ordinary expenditure including interest to £50,133 15*s* 9*d*, leaving a surplus of £4859 6*s* 9*d* From this surplus the sum of £1703 13*s* had to be paid as the annual instalment toward the liquidation of the debt on the West House Of the free surplus £3252 13*s* 8*d* was derived from Craig House and Myreside, and from intermediate patients £8 13*s* 4*d*, amounting together to £3261 7*s* There was a deficit of £417 13*s* 3*d* on the receipts on behalf of patients at the lowest rate of board and patients maintained at the expense of the parochial authorities In the managers' report for 1898 it had been intimated that the pauper rate of board was to be raised from £31 to £32 The managers greatly regretted to have to report that the increase of 20*s* had not been sufficient to meet the expenditure and that therefore they had no alternative but to recommend that the rate of board for pauper patients should be raised to £33 per annum from April 1st. During the year there had been a decrease in the cost of provisions, but a large increase on the cost of fuel, an increase under the head of attendants' wages, and a decrease in the value of labour performed by pauper patients. There would be no change in the rate of board for intermediate patients, which was now £42 per annum. During the year 1899 the sum of £2968 4*s.* 6*d* had been expended on New Craig House, and on the West House the sum of £1479 0*s.* 10*d*, principally in connexion with a new sewerage system. The indebtedness of the corporation on Craig House and the West House together at the end of the year 1899 was £111,655 9*s.* 11*d.* The managers recorded their sense of obligation to Dr. T. S. Clouston for his untiring labours to promote the interests of the institution. In moving the adoption of the report the Lord Provost, after referring to the honourable work carried on by the institution and the satisfactory nature of the report for the year, went on to make some remarks on charities in Edinburgh. He thought that there were too many of these and he was of opinion that the number should be much decreased by uniting some of them. He regretted to say that a number of these charities published no accounts, and he thought that citizens could do much by refusing to subscribe to such charities as were conducted on these methods. The report of the Charity Committee showed that through the agencies of the Charity and Bevan Funds the sum of £675 9*s* 11*d.* had been expended during the past year in supplementing the boards of 60 patients, most of whom would otherwise have been classed among the pauper patients. The report of Dr. T. S. Clouston, physician superintendent, stated that the total number of patients in the asylum on Dec. 31st was 912, including nine on probation The admissions during the year had been 428, of whom 212 were men and 216 women. The total number of patients under treatment during the year was 1373. The admission of private patients who paid the lower rates of board had to be restricted as there was not sufficient accommodation in the West House for that class. There had been no special peculiarity in the causes or characters of the new cases of the year. Alcoholic excess had been the cause of insanity in 25½ per cent. of the cases, this being almost exactly the same proportion as in the preceding five years. He wished that he could report even the beginning of an improvement among the population in this matter. It was precisely those men and women to whose brains alcohol was most dangerous who took it to excess. The persons most apt to acquire the craving for alcoholic liquors were the nervous, the weak, those predisposed to insanity, and persons living sedentary lives or lives of dulness and monotony. If sturdy and vigorous out-door workers only took alcohol in excess it might do them much harm, but there would not be such a large proportion of them thereby rendered insane. There were few persons who had had an opportunity of studying the effect of alcohol on the brain who would not heartily approve of most of the recommendations of Lord Peel's Commission which had recently been published. The Inebriates Act (1898), touching as it did the pressing question only in its criminal aspect, had done very little good and excited very little interest If there was to be legislation on that subject let it be effective. He thought some of their legislators had become victims of the monomania of fear and suspicion in connexion with this matter. From the arguments put forward against such legislation one might suppose that no remedy could be devised for this crying evil without endangering the liberty of the subject and the British constitution itself. With regard to the causation of mental disease it was a fact little realised that purely moral and mental causes played a comparatively small part as compared to bodily and physical causes. In only 11½ per cent. of cases in which the cause was known had trouble and anxiety, worry, or mental shock produced the disease. The remainder of the cases were due to such causes as drink, faulty development, gross brain diseases, strong hereditary disposition, child-bearing, and similar bodily causes. The recent epidemic of influenza had caused more cases of insanity than all the public and private anxiety in connexion with the war. With regard to the question as to whether insanity was increasing, he agreed with the verdict of "not proven" which had been given by the most competent recent investigators. There were, he believed, only two great methods to lessen the great nervous disturbances in civilised societies—viz: (1) to live according to physiological and moral law, and (2) to arrange suitable marriages, and even with these methods in operation it would take many generations to effect any great change. Dr. Clouston then referred to the question of phthisis in asylums. Formerly the phthisis-rate in the Royal Edinburgh Asylum had been a very high one, now it was well below the average. In the last report of the Scottish Commissioners in Lunacy special attention was directed to the question of isolation wards for phthisical patients and he thoroughly agreed with all that had been said in that report. An isolation block would by-and-by have to be provided in the West House. In Craig House they had, so far as he knew, no phthisical patients. Votes of thanks to Dr. Clouston and to the Lord Provost terminated the proceedings.

Faculty of Physicians and Surgeons of Glasgow.

On the evening of March 3rd the Faculty of Physicians and Surgeons of Glasgow gave a professional conversazione to the members of the profession in Glasgow and the west of Scotland in celebration of the tercentenary of their incorporation. There was a large response to the Faculty's invitation, the various rooms being crowded in the course of the evening. The company were received in the large hall by Dr. Hector C. Cameron, President, and the members of the Council. At 7.45 the President in a brief address explained the occasion of the gathering and gave a cordial welcome to the members of the profession present, who included a number of medical ladies. Sir William Gairdner followed with a few sentences of congratulation to the President, in which he made pointed reference to the distinction he had acquired as a surgeon, more especially with reference to the history of antiseptic surgery. In the various rooms demonstrations were arranged with the projection microscope, lantern, &c. Dr John Macintyre and Professor Magnus Maclean gave a number of physico electrical demonstrations illustrative of skiagraphy, phonography, and wireless telegraphy. In other rooms were displayed specimens of new drugs, pharmaceutical preparations, and surgical dressings by Mr. John Macmillan; Messrs. Weiss and Sons and Messrs. C. Ash and Son, Limited, of London, gave exhibitions of surgical and dental instruments; while in various corridors there was a large collection of medical portraits and prints and articles of archæological and artistic interest.

Academic Honours to Medical Men.

Among the six gentlemen to whom the Senatus of Aberdeen University offer the honorary degree of LL.D. at the next graduation are Dr. John Mitchell Bruce, M.A., of London, and Surgeon-Major David Prain, I.M.S, M A., of Calcutta. The career of Dr. Bruce, who graduated M.A. at Aberdeen in 1866 and subsequently proceeded to the degree of M.D. of London University, is too well known to need mention. Surgeon-Major Prain graduated as M.A. at Aberdeen in 1878 with honours in natural science, and as M.B. in 1883 with highest honours, subsequently becoming M.D. He afterwards gained the highest place in the competition for the Indian Army Medical Service, and was appointed curator of the Calcutta Herbarium. On the retirement of Sir George King two years ago he was elected director of the Botanic Gardens, Calcutta. Surgeon-Major Prain has made numerous valuable contributions to the literature of botany.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Hospital in South Africa.

LORD IVEAGH has received a telegram informing him that his hospital had arrived at Cape Town all well and had been ordered to Naauwpoort. Sir William Thomson telegraphed that the whole staff arrived well and in good spirits.

The late Mr. Wheeler.

A portrait of the late Mr. W. I. Wheeler has just been presented to the Lady Superintendent of the City of Dublin Nursing Institution by the past and present nurses of the staff.

The Legal Position of the Medical Officers to County Infirmaries in Ireland.

A legal decision of great interest to medical men has just been pronounced by the Court of Queen's Bench in Dublin. The argument occupied some days and were sustained on each side by lawyers of the foremost position. The facts of the case as stated were briefly as follows. About 18 months ago, just as the new county councils were being installed, Mr. William G. Jacob was unanimously appointed surgeon to the Queen's County Infirmary at Maryborough, in succession to his father, who had been for years a well-known physician in that district. After about a year the legality of his appointment was questioned and the new electing body—consisting under the Local Government Act (1898) of a joint committee, 15 being members of the county council and nine being nominated by the old governors—decided by a small majority that Mr. Jacob had never been formally or legally given the appointment, and they in fact by vote dismissed him, declaring the post of surgeon to the County Infirmary vacant. Dr. John Blaney of Dublin became one of the candidates for the position and was elected by a majority of one. At this stage the legal question became prominent and Dr. Blaney, who was then and is now acting as surgeon to the infirmary, was soon requested by a mandate from the Queen's Bench to show cause why Mr. Jacob should have been dismissed and why he himself should have acted as surgeon to the infirmary. After hearing the arguments the judgment of the court was reserved. It has just now been pronounced and it is of importance, the Lord Chief Justice, Mr. Justice Gibson, Mr. Justice Madden, and Mr. Justice Kenny presiding. Judgment was delivered by the Lord Chief Justice, who said that it was the contention of the plaintiff, Mr. Jacob, that the committee had no power arbitrarily to dismiss him without cause or unless they could show neglect of duty on his part. He contended that the tenure of his office was during good behaviour and that accordingly he could only be dismissed for cause, and that as he was dismissed without cause he was entitled to be reinstated. Looking to the language of the Act, however, he (the Lord Chief Justice) was clear that the meaning and intention of the Legislature was that the appointment should be during pleasure only and not during good behaviour. His lordship referred to the judgment of Chief Justice May in which he used the following words: "The surgeon of an infirmary is merely the paid servant of the governors who receive a salary for his services. The governors may dismiss him at any time arbitrarily." His lordship concluded an elaborate judgment by expressing his high opinion of Mr. Jacob and stating that the legal question prevented their giving him "the redress he sought." The other judges concurring, the application was refused with costs. The decision will have the effect of putting a great deal of power into the hands of the new and almost untried county councils of Ireland. In the above case there does not seem to have been any objection to Mr. Jacob, except that a prominent local Nationalist medical man was preferred by some of the electors, but it is interesting to note that he failed to be the successful candidate.

The Ulster Medical Society.

A meeting of this society (which was very largely attended) was held in the physiological department of Queen's College on March 1st.—Dr. Lorrain Smith gave a demonstration of Haldane's Method of estimating the Oxygen-carrying Power of Blood by Ferro-cyanide of Potassium and an account of observations on anæmia with demonstration of the method employed. The latter paper was of great interest and of original research. It was based on a series of cases observed at the Royal Hospital as well as on three private cases placed at Dr. Lorrain Smith's disposal by members of the medical profession.—Dr. C. Kevin, Professor J. W. Byers, Professor J. A Lindsay, and Dr. A. Dempsey took part in the discussion which followed.—Dr. Lorrain Smith showed a series of Pathological Specimens of very varied nature.—Professor W. H. Thompson read a paper on Degenerations resulting from Lesions of the Temporal Lobe, which was discussed by Dr. P. Redfern and Professor J. Symington.—Professor J. Symington and Dr. J. Tennant displayed and demonstrated a series of specimens (sectional) illustrating the Anatomy of the Female Pelvic Viscera, and Professor Symington and Dr. J Craig showed a series of specimens of pathological interest obtained from the dissecting-room and specimens showing the Topographical Anatomy of the Mammary Gland in Nulliparæ.

The Proposed New Infectious Diseases Hospital.

The Public Health Committee of Belfast, seeing that it is impossible to carry out the Notification of Infectious Diseases Act without the establishment of a special hospital for the treatment of zymotic cases, have decided to recommend the erection of one, a course of action approved of by the medical inspectors of the Local Government Board. They are of opinion that such an hospital should be erected on the Purdysburn estate, authority for the construction of which has already been given by the City of Belfast (Hospitals) Act, 1898 They recommend that this hospital should be constructed in pavilions of about 20 beds each, with a total of about 150 beds, with administrative, washing, disinfecting, and ambulance arrangements, and a special pavilion and separate accommodation for the isolation and treatment of small pox cases, and they estimate the cost of constructing and maintaining this hospital as follows: cost of building and furnishing complete 150 beds at £300 per bed, £45,000; annual outlay for 40 years on a 3 per cent. basis sinking fund and interest, £1950; cost of maintaining 150 beds at £40 per bed per annum, £6400. That such an hospital is needed, and, indeed, most urgently required, in a large city like Belfast, where accommodation for infectious diseases is very meagre, is admitted by everyone, but apparently, judging by what occurred at the meeting of the city council on March 1st, there is a difference of opinion as to the proper site. A large deputation of medical men appeared before the council appointed at a specially-called meeting of the medical profession on the previous day, and stated that they now again endorsed a memorial passed by a number of medical men in 1897, and presented at that time to the Lord Mayor and council protesting against the Purdysburn site. In this memorial it is stated that the transference of fever patients for a distance which would vary from two or three to seven or eight miles would be dangerous to the more serious cases, would in all probability aggravate the severity of the attack, and prejudice the patients' prospects of recovery. A hospital should be near enough to permit of daily inquiries being made and to render possible the prompt summoning of friends in case of urgent danger suddenly arising, as frequently occurs in fever cases. It was also urged that the medical service would be more costly at such a distant place and that the distance from Belfast would interpose much difficulty and delay in obtaining additional medical advice in cases of urgent danger. Further, such an hospital would be unsuitably placed for the purposes of the training of medical students. Believing, then, that a hospital at Purdysburn would involve needless risk of life, would entail serious hardships upon the working classes in their relations to their sick relatives, would create much discontent and friction in the administration of the Notification of Infectious Diseases Act, would subject the ratepayers to unnecessary expense, and would prejudice the cause of medical education in Belfast, the memorialists prayed that the proposal should be reconsidered and some convenient and more accessible site be selected. The deputation, who suggested as a suitable site the grounds of the old asylums in Grosvenor-street, having been heard the matter afterwards was discussed in the council. The chairman of the Public Health Committee (Dr. Alderman Graham) said he regretted that one greatly favourable site for the Infectious Diseases Hospital could not be obtained near the city, but he regarded the Purdysburn situation as the most suitable one for such an institution. He stated that, as regarded the question of distance, the most recently constructed hospitals in the kingdom occupied sites no nearer the cities than Purdysburn was to Belfast. He gave as examples, Glasgow, Manchester, Newcastle, Nottingham, Bristol, and Leeds. The corporation seemed to be much divided and the chairman of the committee of the new asylum, which is situated at Purdysburn, protested against putting at Purdysburn an infectious diseases hospital as nothing should be done to deteriorate or destroy the effect of the future asylum. An amendment to refer matters was defeated (14 voting for and 24 against) and the motion to adopt the report of the Public Health Committee and to go on with the erection of the infectious hospital at Purdysburn was carried. One of the medical members of the corporation voted against the site at Purdysburn, while six voted in favour of it It is expected that the erection of the new fever hospital at Purdysburn will be begun at once.

Health of Belfast.

Between Jan. 21st, and Feb. 17th, 1900, 200 cases of zymotic disease have been notified, and of these 57 were scarlet fever, 48 typhoid fever, 34 erysipelas, and 22 diphtheria. The death-rate was 26 1. There is no doubt that there is a widespread epidemic of mild scarlet fever, but the type of the disease is not severe and no deaths have been reported Nearly one-half of the deaths from zymotic diseases was due to whooping-cough. While influenza has been prevalent the mortality has been low. Indeed, the general death-rate of the city has been below the average of the large towns of Ireland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Disinfection after Measles.

AT the meeting of the Academy of Medicine held on Feb. 20th M. Vallin laid great stress upon extending the regulations as to disinfection so as to include measles. In 1895 disinfecting operations were undertaken in 38,000 cases and during 1898 in 63,000, being mainly cases of notifiable disease. In the case of measles disinfection is hardly ever asked for or carried out and thereby exists a very real danger. Measles is far more infectious than is generally believed; instances are even known of persons who have contracted the disease from brushing the clothes worn by a patient suffering from measles. In any case if it is important to destroy the actual measles germ it is equally important to destroy those of the diseases which so often complicate measles—as, for instance, those of broncho-pneumonia. In M. Vallin's opinion measles should at once be added to the list of those diseases in which disinfection is absolutely necessary.

The Fraudulent Supply of Diseased Meat.

The police of Paris have just laid hands on a vast fraudulent organisation for evading the precautionary measures drawn up by the authorities for inspecting the meat distributed for consumption in the suburbs of Paris. Both for Paris and the suburbs all animals destined for food have to be killed in public slaughter-houses, where the strictest watch is kept by the municipal veterinary surgeons, who forbid the delivery to the butchers of any meat which exhibits the slightest suspicious signs. Elaborate regulations have been laid down as to the various diseases which render meat unfit for the food of man, and naturally enough tuberculosis is the complaint most rigorously watched for. The swindlers who have been arrested made up a vast organisation which used to buy up from the farms of the eastern provinces and even in Germany such animals as, owing to disease, would have been refused for slaughter at the abattoirs and, moreover, they bought them dirt cheap. These animals were then conveyed in regular herds to a small place near Paris and killed in sheds built at the bottom of an old quarry. Under cover of night the meat was taken away by the accomplice butchers and re-sold in the various suburban shops. In connexion with this clandestine slaughter-house the firm had a kind of cemetery where those animals were buried the meat of which was too bad for even the swindlers to risk its sale in the market. Ivry was the place where the fraud was discovered and the official inquiry shows that the organisation was singularly complete. It is extraordinary that the slaughter-house, which was in full work, should never have attracted the attention of the villagers, but it must be remembered that all killing was done by night and that the slaughtermen were all Germans who did not understand a word of French and were therefore unable to engage in imprudent conversation with the neighbours.

Tuberculosis and the National Convalescent Homes.

The Minister of the Interior decided that from Jan. 1st, 1900, no tuberculous patient shall be received at the convalescent homes of Vincennes or Vesinet to which patients from the Paris hospitals are sent. The authorities of these homes are forbidden to receive any patient who does not bring a certificate bearing the words, "No sign of tuberculosis of the respiratory tract." This is a perfectly legitimate measure to take and had its inception in the fact that the population of a convalescent home is an admirable breeding ground for the tubercle bacillus, owing to the low powers of resistance and general feebleness of health shown by convalescents. The measure, however, carries with it as a corollary the erection of buildings for tuberculous patients who are gradually being more and more excluded from general hospitals. A proposal has been submitted to the Committee of the Chamber (*Bureau de la Chambre*) by M. Fleury-Ravarin, the deputy for the Rhône, with the object of creating a national Anti-tuberculosis Institute. It is intended to be a scientific establishment for the study of the treatment of tuberculosis and for experimental research into the various ways of curing this malady, which is responsible for 750,000 deaths annually in France alone and those mainly among the working classes. A large sanatorium which will receive patients free will shortly be opened in the Lyons district on the mountains of Bugéy. In the department of the Nord a subscription opened to found a sanatorium brought in on the first day 35,000 francs in donations, after a meeting called by Professor Ausset. Finally, it is hoped that the large sanatorium which has been so many years building will be opened before long at Angerville under the auspices of the city of Paris.

The Therapeutics of Cacodyle.

Treatment by cacodyle, on which subject information has already appeared in THE LANCET,[1] was introduced by Professor Armand Gautier. A large number of physicians have made trial of it and it is now possible to arrive at a fairly exact estimate of the value of the treatment. A discussion took place at a meeting of the Society of Hospital Physicians, held on March 2nd, which was preceded by a paper communicated by M. Widal and M. P. Merklen, which followed a paper read by M. Dalché at the preceding meeting. M. Dalché was most optimistic; even when given as a pill the drug had produced no ill effects in patients except that their breath acquired a slight odour of garlic, neither had he ever noticed the occurrence of diarrhœa nor any uneasy feelings in the stomach. In two cases where the drug was given by injection one patient complained of pain. M. Dalché's patients were almost all tuberculous. Three were undeniably cured, in four their condition improved to a marked extent, especially as regards the way in which they put on weight, acquired more muscular force, and manifested greater renal activity. Two cases showed no particular results and two got worse, but they were patients far advanced in tuberculosis. Two patients who showed no signs of pulmonary tuberculosis but were suffering respectively from Addison's disease and cancer of the stomach derived no benefit from the treatment. M. Hayem preferred to give the drug by hypodermic injection rather than by the mouth, which was apt to produce gastric intolerance, or by the rectum, which method often gave rise to severe lumbar pains. M. Danlos also preferred the hypodermic method, not only because the drug thus administered was better borne but because by this means it was possible to give much larger doses, as much as 40 or even 80 centigrammes. As for cacodylate of sodium being transferred into the toxic oxide of cacodyle, he had *never known* such a thing to be absolutely demonstrated. M. Galliard had never seen any untoward results even with doses of 20 or 40 centigrammes given by the mouth. He was well satisfied with the drug in tuberculosis; the strength returned and the patient put on weight; there was, however, but little alteration in the pulmonary conditions. M. Widal and M. Merklen had used daily hypodermic injections in doses of from five to 10 centigrammes. In advanced cases of tuberculosis where there was much ulceration this treatment had not much effect, but in early cases the appetite rapidly improved and they considered that this method of treatment was an admirable adjuvant to other methods either therapeutical or hygienic. In leucocythæmia cacodylate improved the appetite and increased the strength but had not much effect on the general course of the disease. With regard to its effect on the blood careful daily observations showed but little difference in the white corpuscles, but the number of the red was largely increased. Professor Armand Gautier closed the discussion, in which M. Hirtz, M. Rendu, and M. Barth also took part, by insisting on the necessity of administering the drug solely by the hypodermic method unless it was desired to obtain poisonous effects from the breaking-up of the compound in the digestive tract.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Post Nubila Phœbus.

"A BUCKET or two of water whipped up into a cloud," says Tyndall, "will obscure the noblest mountain; but let the sun come out, and the cloud vanishes, leaving the mountain all the more prominent for its temporary eclipse." Continental critics—and their name was Legion—who saw in the initial reverses of the British arms the definitive triumph of the Boers have been giving point to Tyndall's illustration; and to do them justice, they spared no effort to drive it home. Never was the mythopœic tendency of journalism more characteristically in evidence than in the "news" hailing from Paris, from Brussels, from Munich, from Berlin—"news" as to British disasters of every kind and corresponding Boer successes. The Arkansas editor who would have dismissed Shakespeare from his reporting staff as wanting in imagination would have had no difficulty in "suiting himself" from the publishing offices of French, Belgian, or German newspapers; while the "pictures" in the illustrated press of these countries were equally remarkable for what (to put it mildly) I may call "creative power." Now, with a turn of the wheel, not of fortune, but of "manifest destiny," news and pictures alike have vanished like Tyndall's cloud or Shakespeare's "baseless fabric of a vision," leaving not a "wrack" behind but that of the Boer cause. Italy, as I have already shown,[1] from nearly the outbreak of hostilities kept her head, like Tiresias in the Shades—

---

[1] THE LANCET, Nov. 18th, 1899, p. 1408.

οἴῃ πέπνυται, τοὶ δὲ σκιαὶ ἀΐσσουσιν
(She only wise, the rest like shadows flit)—

and in her steady pro-British attitude placed herself on a coign of vantage from which she can now enjoy the discomfiture of those "economists of truth" (to use King George III.'s phrase), her pro-Boer continental sisters. Except for her insignificant Socialist and Jesuit press (the "Red Devil" and the "Black Devil," according to Bismarck, always make common cause against real civilisation), except for the *Secolo* and the *Voce della Verità* (for instance), her printed comments on the campaign leave her nothing to apologise for or to retract, but, on the contrary, entitle her to the British gratitude conveyed through Lord Rosebery to her Foreign Minister, the Marchese Visconti Venosta. Her Red Cross organisation, moreover, distinguished itself honourably from that of other nations in its strict impartiality towards the belligerents—at least, the world heard of no agents of hers in that capacity giving active help or supplying information or war material to the Boer army. I refer to all this, little germane as it may seem to medical correspondence, because I have had frequent occasion to be very plain-spoken as to Italy's backwardness in public hygiene and in medical education and as to the policy of some of her professional men towards the British-American practitioner in her winter cities. But where I can honestly give praise to her I never withhold it—certainly not at present when her demeanour towards the British cause has been loyal even to cordiality and when she is reaping the fruit of it by attracting, at the expense of her Anglophobic neighbours, the ever-welcome *English-speaking sojourner*.

Public Health on the River Plate.

Italy is in close touch with the Rio de la Plata, thanks to her very numerous compatriots in Uruguay and the Argentina, and among the advices that reach her not only by every mail but almost daily by telegraph from those regions the public health fills a large and interesting place. Their summer corresponds to the Italian winter and both, in either latitude, have been exceptionally severe. From Montevideo, it is announced, the heat has been as much as 38° C. in the shade every afternoon and there has been quite extraordinary drought, even to menacing the ruin of the crops and the destruction of cattle. While the public health in Uruguay has been excellent, especially at Montevideo, where the bathing season has attracted many visitors from the neighbouring communities, it has in the Argentina been very much the reverse, pestis bubonica having appeared in force at Rosario di Santa Fè, the second city of the Republic, and having seemingly effected a foothold in Buenos Ayres itself. On Jan. 27th Rosario was isolated by a sanitary cordon, railway traffic was suspended, and communication by river was subjected to a ten days' quarantine The bubonic infection is considered to have come from Asuncion in Paraguay where the pestis has been epidemic for several months. At present the number of patients isolated amount to 11, and although the population keeps tranquil the almost total arrest of business causes grave commercial and economic difficulties. In Rosario itself it is stated that a whaler having a cargo of grain in which a multitude of plague-stricken rats were burrowing imported the disease, the first case having declared itself in a mill to which the grain was sent and the first victim being a porter of the establishment who helped to unload the cargo. Subsequent reports announce the cases at Rosario as reaching from eight to ten per day, while in Buenos Ayres they vary from four to five. In both cities Government and municipality alike have at their disposal every resource for circumscribing and overcoming the invader and are utilising it so energetically that they soon hope to register a clean bill of health. Uruguay immediately on the facts becoming known established a ten days' quarantine for all arrivals from Rosario and a five days' quarantine for those from Buenos Ayres and is reaping the reward of its vigilance in its excellent sanitary conditions, though from the west and from the east it was exposed to the unwelcome visits of a steamship with cases of beri-beri and yellow fever on board and of a liner hailing from Rio and Santos, also carrying patients suffering from the latter disease.

March 4th.

Obituary.

THOMAS SCATTERGOOD, M.R.C.S. ENG., L.S.A.

MR. THOMAS SCATTERGOOD of Park-square, Leeds, who died somewhat suddenly on Feb. 22nd, had for many years been one of the foremost representatives of the medical profession in that city. At the time of his death he had just completed his 74th year, having been born on Feb. 14th, 1826, in Huddersfield, where his father, the Rev. Thomas Scattergood, of the Methodist New Connexion, was stationed. His professional education was commenced at the medical school of Newcastle-on-Tyne and continued at the Leeds Medical School until he became qualified in 1850 as M.R.C.S. Eng. and L.S.A. He soon established himself in practice in Leeds, and having at a comparatively early period of his career acquired a reputation as a toxicologist and medical jurist he was called upon to give evidence in several cases of criminal poisoning, one of the most celebrated being that of Mary Ann Cotton, who was suspected of having poisoned 16 persons and was executed at Durham in 1873 for the poisoning of her own child. Mr. Scattergood's most important work was done in connexion with the Leeds Medical School and Yorkshire College, and is well epitomised in the following paragraphs of a resolution of the Board of Medicine passed on the day after his death:—

"The members of the Board of Medicine of the Yorkshire College desire to place on record their sense of the irreparable loss which the School of Medicine has sustained by the death of Mr. Thomas Scattergood, who for 55 years had been intimately connected with the school, first as a student, then as lecturer in chemistry, and afterwards as lecturer in forensic medicine, and who had also held the office of dean from the time of the union of the school with the college in 1884 until his death. . . . His discretion, tact, and clearness of vision were invaluable in the negotiations which led to the union of the school with the college. His activity and success in raising funds for the endowment of the chair of Physiology enabled the department of medicine to enter upon its new career with an important improvement of the staff. And a few years later his enthusiasm, his faith in the future, and his firm determination to better the conditions of medical education mainly led to the rebuilding of the school."

One of his medical colleagues, writing in the *Leeds Mercury* of Feb. 27th, says:—

"He had been actively connected with the Leeds School of Medicine for nearly 50 years, being almost the last survivor of those who formed the lecturing staff of the old Medical School in East Parade, and was present at the opening of the newer building in Park-street in 1865 by Sir James Paget. . ... It was in the long and tedious negotiations preparatory to the amalgamation of the Medical School with the Yorkshire College that the splendid qualities of Mr. Scattergood were seen to the greatest advantage. He acted as chairman of the building committee of the present handsome school in Thoresby-place, and without exaggeration it may quite fairly be said that it is a permanent memorial of him."

To mark their sense of the great [illegible]]ered by Mr. Scattergood his colleagues and some [illegible] had decided a few months ago to have his portrait painted by Sir George Reid, ex-President of the Scottish Academy. At the time of his death the portrait was, fortunately, nearing completion, so it is hoped that the medical department of the Yorkshire College will have a permanent memorial of one who in his own unostentatious way never wearied of advancing its interests. The funeral took place at the Lawnswood Cemetery on Feb. 28th in presence of a large and sympathetic assemblage. The service was conducted by the Rev. Charles Lemoine, pastor of the East Parade Congregational Church, of which Mr. Scattergood had been a member since 1853 and had also for a long time been one of the deacons.

---

[1] THE LANCET, Dec. 23rd, 1899, pp 1750-1.

THOMAS GUY, M.D. HEIDELB., F.R C.P. LOND., M.R.C.S. ENG.,

INSPECTOR GENERAL OF ARMY HOSPITALS (RETIRED).

INSPECTOR-GENERAL GUY, who died at his residence in Pencester-road, Dover, on March 2nd, may be said to have belonged to a medical family, for his father and grandfather were medical men, and the late Dr. William A. Guy, F R.S., was his brother. Thomas Guy was born at Chichester in 1819, studied medicine at Guy's Hospital, and was admitted M.R C.S. Eng. in 1840. In 1841 he graduated as M.D. of Heidelberg University and in 1842 he entered the army as assistant surgeon. His subsequent steps were surgeon in 1853 and surgeon-major in 1862. He served throughout the Abyssinian campaign of 1867–68 as superintendent of hospital ships, was principal medical officer of the European troops at Zoulla, the British base on the Red Sea, was mentioned in despatches and promoted to be deputy-inspector-general of hospitals in 1868, and received a medal. He retired from the service in 1872 with the honorary rank of inspector-general. In 1859 he was admitted M.R C.P. Lond., and in 1878 became a Fellow of the College. In 1870 he translated from the German Professor Esmarch's treatise on "The First Dressing of Wounds on the Battlefield," and during the Franco-German War he acted as director of the English ambulance.

WILLIAM McNEILL WHISTLER, M.D. PENNS., M.R.C.P. LOND., M.R C.S. ENG.

DR. W. McNEILL WHISTLER, physician to the London Throat Hospital, and brother of the well-known painter, died at Bickenhall-mansions, Gloucester-place, on Feb. 27th, aged 63 years. His medical education was received at the University of Pennsylvania where he graduated as M.D. in 1860. During the American Civil War he served as an assistant surgeon in the Confederate Army and on the conclusion of hostilities came to Europe where he resumed medical study in Paris and at St. George's Hospital, London. Intending to practise in England he took the diplomas of M.R.C.S. Eng. in 1871 and M.R.C P. Lond. in 1876. Dr. Whistler was formerly physician to the Hospital for Diseases of the Throat and Chest, and Honorary Physician to the National Training School for Music. He was a member of a number of medical societies in England, France, and America, and had been President of the British Laryngological, Rhinological, and Otological Association. Dr. Whistler published "Lectures on Syphilis of the Larynx: Lesions of the Secondary and Intermediate Stages." In addition to being author of articles in the "New York Archives of Laryngology" and in Quain's "Dictionary of Medicine," he contributed several papers to THE LANCET and other medical journals.

ROBERT GOLDSWORTHY TUCKER, M.R.C.S. ENG., L R C.P. EDIN.

MR. TUCKER, who died at his residence in Southend, Essex, on Feb. 23rd, was formerly in practice in Farningham and Swanley where he was for nearly 20 years one of the best-known and most esteemed members of the community. He was the son of a well-known surgeon who was himself the first to pass the then new examination for the Fellowship of the Royal College of Surgeons of England. At St. Bartholomew's Hospital, where he received his medical training, he excelled greatly, not only in his professional studies, but also in physical exercises. In 1873 he became qualified as M.R C S. Eng. and L.R.C.P. Edin., and in the following year he took a share in the practice of Messrs. Ashurst, Tucker, and Smith, at Farningham, Kent. About 1887 he removed to Swanley Junction, a new and rapidly increasing place, where he made for himself a separate and extensive practice. He became surgeon to the St. Bartholomew's (Kettlewell) Convalescent Home, to the Swanley Little Boys' Home, to the Swanley Horticultural College, as well as to the railway staff, and he also filled several other local offices. In May, 1897, however, he decided, for family reasons, to dispose of his Swanley practice, and he removed to Southend-on-Sea, where he again quickly made his mark and where he died, at the early age of 47 years. The fatal result was due to pneumonia following an attack of influenza. As a medical man he was kind and attentive. His memory is widely and deeply cherished by his former patients whose confidence he possessed to a rare degree and whose sympathy followed him to the end. His funeral took place on Feb. 27th at Prittlewell, near Southend.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. Cargill Shaw, Professor of Neurology in Long Island College, Brooklyn.—Dr. Emile Blanchard, Professor of Zoology in Paris.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The following gentlemen passed the First Examination of the Board in the subjects indicated:—

Chemistry and Physics.—Bertram Raleigh Bickford, Charing Cross Hospital; Robert Daniel Bridger, Guy's Hospital and Birkbeck Institute; John Braybrooke Binns and Edward James Cooper Smith, St. Bartholomew's Hospital; Patrick D. McIvor Campbell, St. Mary's Hospital; Francis William Cooper, Guy's Hospital; Owen Cunningham P. Cooke, Malcolm Ogden Cruickshank, Harry W. Beresford Danaher, and John Burnaford Dunstan, London Hospital; John Rees Davies, University College of South Wales, Cardiff; Robert Deane, University College, London; George Fanning Denning, Charing Cross Hospital; Kenneth A. Crawford Doig, Westminster Hospital; Arthur Melville Dowdall, University College, Liverpool; George Bennicke Edwards, London Hospital; Harry Arthur Fenton, Stephen Field, and Walter Taylor Finlayson, St. Mary's Hospital; Charles Breame Fowler, Charing Cross Hospital; John Alan Campbell Greene, Guy's Hospital; Kenneth George Haig, Oxford University; George Wykeham Heron, Westminster Hospital; Mark Oliver Hunter, St. George's Hospital; William Hayward Hamilton and James Reginald Kemp, St. Bartholomew's Hospital; Charles Frederic Kernot, Cambridge University and London Hospital; John Lascelles, St. Mary's Hospital; Idris Naunton Morgan, University College of South Wales, Cardiff; Charles Sculthorpe Morris and Maurice John Mottram, Guy's Hospital; Farndon Groom Mountain, St. Bartholomew's Hospital; Hamish Nicol, Westminster Hospital, Robert Woodall O'Dowd, Mason College, Birmingham; William Stewart Orton, Guy's Hospital; Christopher Parker, Westminster Hospital; Edward Campbell Pope, St. Paul's School, West Kensington; Ronald Holt Preston, St. Mary's Hospital; Ralph Raby and Leslie Rawes, St. Thomas's Hospital; George Hooper Rains, Clifton Laboratory; Alfred Ernest Rowlett, Guy's Hospital and Wyggeston School, Leicester; Herbert Bodley Scott, St. Bartholomew's Hospital; Francis George Snoad, Mason College, Birmingham; John Edmund Spiller, Guy's Hospital; John Douglas Staley, Owens College, Manchester; George Morley Arundel Thomas, University College of South Wales, Cardiff, Edinburgh University, and St. Mary's Hospital; Guy Tyrrell Verry, St. Bartholomew's Hospital; Bertram Joseph Wakley and James Marsden Wall, St. Thomas's Hospital; William Arthur Weatherell and Solomon James Weinberg, Owens College, Manchester; Arthur Sydney Webley and Ralph Kuper White, St. Mary's Hospital; Stanley Martin Wells, Forest School, Walthamstow; Vernon Northwood Whitamore, Charing Cross Hospital; and Ernest Douglas Wolff, King's College, London.

Practical Pharmacy.—James W. Woodhams Adamson, St. George's Hospital; Robert Grenville Anderson, Guy's Hospital; Samuel Ernest Atkinson, Yorkshire College, Leeds; Harry Cecil Baker, St. Mary's Hospital, Charles John Battle, St. Thomas's Hospital; William Nichols Blachford and Richard Osmond Bodman, University College, Bristol; Isidore McWilliam Bourke, St. George's Hospital; George Brocklesby Davis, Cambridge University and London Hospital; Clarence Hamul Denyer, Guy's Hospital; Louis Cornelius Driscoll, Charing Cross Hospital; Harry Denny Duke and Herbert Wortley Fisher, London Hospital; Leonard Erasmus Ellis, St. George's Hospital; Edwin Wallace Goble, Guy's Hospital; John Leopold Goldstein, Arthur Hildebrand Jacob, Norman Bremer Vickers Jacob, George J. Williams Keigwin, and Andrew Macrae, London Hospital; Archibald Malcolm Mackintosh, St. Mary's Hospital; Paulin John Martin, Oxford University and St. Bartholomew's Hospital; William Charles Mence, St. Thomas's Hospital, Frank Morgan, Westminster Hospital; Stanley Parkes Mummery, St. George's Hospital; William L'Estrange Matthews and Robert Woodall O'Dowd, Mason College, Birmingham; John H. Le Bouverie Page, St. Mary's Hospital; Harold Thornbury

Palmer and Allen Fledger Piggot, Guy's Hospital; Percy George Pavitt, Middlesex Hospital, James Farquharson Powell, St. George's Hospital; George Russell Rew, King's College, London; Russell John Reynolds, private study; Herbert George Rickman, St. Mary's Hospital; Cyril Stephen Stokes Rigby, Mason College, Birmingham; Godfrey Faussett Rugg and Robert Spears, University College, London; Leonard Douglas Saunders, St George's Hospital, Charles Newham Slaney, private study; John Salmon Smith, Middlesex Hospital, Eugene Dunbar Townroe and Frederick George Walker, St. George's Hospital; Walter Frederick Hamilton Vaughan and Hardy Vesey Wells, St Mary's Hospital; Frank Edward Wavte, Owens College, Manchester; and Reginald Cameron Wilmot, St. Bartholomew's Hospital

Elementary Biology.—Arthur Reginald Beaumont and Osborne Black, Guy's Hospital, Charles Murchison Bernays, St Thomas's Hospital; Edward John Blewitt, London Hospital; John Taylor Bowker, Owens College, Manchester, Harold Clapham, St. Mary's Hospital; Francis William Cooper and Hugh Palliser Costobadie, Guy's Hospital; Harold G Shackleford Courtney, St George's Hospital; Harold Ernest Cribb, Charing-cross Hospital; Thomas Henry John Crookes, St. Bartholomew's Hospital; Arthur Humphry Curtis, University College, London; William Leonard Dickson, Middlesex Hospital; Harold Denny Duke, London Hospital; Hyacinth Lloyd Field, St. George's Hospital; Arthur George Finch and Charles Breame Fowler, Charing Cross Hospital; William Henry France, South-West Polytechnic Institute, Chelsea; John Stanley France, and John Alan Campbell Greene, Guy's Hospital; Percy Gully, Charing Cross Hospital; Charles Norman Hampson, Owens College, Manchester; Arthur Lewis Heiser, Middlesex Hospital, Albert William Hill, Yorkshire College, Leeds; Walter de Marchot Hill, St. Bartholomew's Hospital; Samuel William Iles, Guy's Hospital; Walter Greig Jack, St. George's Hospital; Charles Frederic Kernot, Cambridge University and London Hospital, Cameron Lamb, Oxford University and Guy's Hospital, William A. Thomas Lloyd, George William Mason, and Echlin Storry Molyneux, London Hospital; Herbert Cecil Malleson, Birkbeck Institute; Eric Stewart Marshall, St. Bartholomew's Hospital, Charles Sculthorpe Morris, Louis Joseph Patterson Clavier and Edward Crosby Peers, Guy's Hospital; John J. Papanicoly, James Wesley Peatt, and Geoffrey Ratcliffe Plaister, London Hospital, Vining Gedney Joseph Paul, St. Mary's Hospital; William Baly Peacock, King's College, London, Gordon Christopher Pounds and Charles Puxley, Charing Cross Hospital, Gerald Charles Frederick Robinson, Richard Pugh Rowlands, and John Edmund Spiller, Guy's Hospital; Harold H. Walford, St. *George's Hospital; Gerald Maberly Taylor,* London Hospital; Ingram Thomas Walker, St. Thomas's Hospital; and *Theophilus* Ralph Wallenburgh, Owens College, Manchester.

Materia Medica—Alexander Farrington, Cambridge University and *St Bartholomew's Hospital, Kenneth Weldon* Goadby, Guy's Hospital; and John May Herbert Munro, University College, Bristol.

UNIVERSITY OF CAMBRIDGE.—On March 1st the following degrees were conferred:—

Doctor of Medicine—J. A. K Renshaw, M A, Trinity College.

Bachelor of Medicine and Bachelor of Surgery—*C. H. Barnes*, B A, and W. T. Mullings, B A, Christ's College

M A (honoris causâ)—F. G. Hopkins, M B, B Sc. Lond., University Lecturer in Chemical Physiology

Dr. Langley, F.R S., has been appointed deputy for Sir Michael *Foster*, M.P., and will have charge of the Physiological Department till the end of the next academical year.—It *is proposed to assign about* £12,000 from recent benefactions for the erection of new buildings *for* pathology, pharmacology, and medicine. An additional sum of at least £20,000 will have *to* be *found to provide* adequately for the requirements of these *departments* and the University is still in need of further gifts to this end.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—The annual meeting of this institution was held on Feb. 19th under the presidency of Major Whitting. The medical report stated that 232 in-patients had been *admitted*, against 269 in 1898. The out-patients and casualties numbered 1353. The provident dispensary had 2332 members, an increase on the preceding year. The financial statement showed that the receipts amounted to £2250 and that a favourable balance of £233 remained.

THE LATE DR. J. BROOM.—Dr. John Broom died at his residence in Clifton on Feb. 26th in his fifty-eighth year after a short illness. The deceased gentleman received his medical education at the medical schools of Liverpool, Sheffield, and the London Hospital and qualified as L R C P. Irel, and L R.C S Edin. in 1870, three years later graduating as M.D. of Brussels University with distinction. Dr. Broom shortly afterwards commenced practice in Sheffield and in 1877 went to Clifton as partner with the late Dr. T. E Clark, the partnership terminating in 1879. Dr. Broom had a large practice and was extremely popular amongst his patients. He allowed himself so little relaxation and holiday that his work told seriously upon his health during the last few years.

UNIVERSITY OF DURHAM FACULTY OF MEDICINE.—The Secretary of State for War having been pleased to avail himself of the powers conferred upon him by Royal warrant recently offered to the University of Durham three nominations to the Royal Army Medical Corps which have been filled by the appointment of the following gentlemen:—Mr. James Andrew Hartigan, Mr. Charles S. Smith, and Mr. Harold Ben Fawcus, all of whom are graduates in medicine and surgery of the university. Surgeon-Captain Wresford who accompanies the South African battery of the 1st Northumberland Volunteer Artillery, and Surgeon W L W. Walker, who has been attached to one of the South African companies of the Northumberland Yeomanry, are also graduates of Durham. Of the present and former students of the University of Durham College of Medicine eight have volunteered for service in South Africa and are either at the front or on their way there.

ROYAL FREE HOSPITAL.—The seventy-second annual court of the governors was held at the hospital in Gray's Inn-road, W C, on Feb. 28th, the Earl of Stamford presiding. In moving the adoption of the report Lord Stamford remarked that the work of the hospital had been carried on in the most efficient manner during the past year. 2117 patients had been treated in the wards, while over 35,000 out-patients and casualties had received advice and medicine. His lordship referred to the special claims which the hospital had upon public sympathy and support in that admission to its benefits was absolutely free, also that it had been the first general hospital to appoint a trained almoner to see the applicants for relief, and that it afforded opportunities for clinical instruction to women medical students. Mr. Charles Burt, the chairman of the weekly board, stated that in order to provide better accommodation for the nursing staff it was proposed to build a fourth storey over the side portions of the rear central block, the cost of which is estimated to be not less than £5000. In view of the pressing claims now being made upon the public in connexion with the war in South Africa the committee must rely upon the generous assistance of the friends of the charity to provide the necessary funds, not only for these much-needed improvements but also for the maintenance of the work of the hospital. Mrs Scharlieb, M.D Lond, moved a resolution expressing the thanks of the governors to Mrs Webb and other friends for their generous gift of a new museum and bacteriological laboratories which had been erected as a memorial of the late Miss Mabel Webb, M B. Lond., formerly curator of the museum. At the close of the proceedings Lady Reay, C.I., formally opened the new museum.

SCOTTISH NATIONAL RED CROSS HOSPITAL.—A public meeting was held on March 2nd in the Merchants' Hall, Glasgow, for the purpose of promoting the Red Cross scheme of the St. Andrew's Ambulance Association for establishing a Red Cross Base Hospital in South Africa. The Lord Provost presided, and there was a large and influential attendance. Lord Overtoun, after moving "that this meeting approve of the formation of the Red Cross Branch of the St. Andrew's Ambulance Association for Aid to the Sick and Wounded in War," said that the association, which was founded in 1882 and received a Royal Charter in 1889, had two objects, one to help the suffering in time of peace and the other to aid the wounded in time of war. There was now a great field for a Red Cross department in connexion with the association. The Rev. Dr. McAdam Muir seconded the motion, which was carried unanimously. The Lord Provost moved "that this meeting cordially recommends to the sympathy and liberality of the people of Scotland the scheme for establishing at Cape Town or elsewhere in South Africa, as the military authorities may direct, a base hospital to be called the Scottish National Red Cross Hospital." The Corporation of Glasgow had offered the Ruchill Hospital for the reception of wounded men who might be sent home, but the superiority of a base hospital in South Africa over a hospital at home was evident, for it would be not only in a most exhilarating climate—to which, indeed, patients were sent from this country in order that they might recover—but the men would be saved from the discomforts of the voyage home and of being conveyed to the nearest hospital after they landed. As the result of an appeal made during the last few days £10 857 had been received. Sir Thomas G. Glen-Coats, Bart., seconded the motion, which, supported by General

Chapman and Professor Ramsay, was adopted. Sir William Laird moved, and it was resolved, that a committee be appointed to coöperate with the council of the association. On the motion of Dr. G. C. Beatson, chairman of the council of the association, a vote of thanks was awarded to the Lord Provost for presiding.

Medical High Sheriff.—Dr. A. Garrod Thomas, J.P., of Clytha Park, Newport, Mon., has been appointed High Sheriff of Cardiganshire.

Royal College of Physicians of Ireland.—At the request of the Secretary of State for War the President of the Royal College of Physicians of Ireland has nominated Mr. F. G. Fitzgerald, L.R.C.P. & S. Irel., to a commission in the Royal Army Medical Corps.

Anti-vaccinationists as Vaccination Officers.—At the meeting of the Liskeard Board of Guardians held on Feb. 24th Mr. Preston Thomas, of the Local Government Board, who attended the meeting, said that he did so at the express wish of Mr. Henry Chaplin, M.P., in reference to the refusal of the Local Government Board to sanction the appointment of an anti-vaccinationist as vaccination officer for the Collington district. After some discussion it was decided to agree to the wishes of the Local Government Board and to advertise for a vaccination officer for the district and that the words "no anti-vaccinationist need apply" should be added to the advertisement.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Lunacy Bill.

Several amendments were made in the Lunacy Bill during its passage through Committee in the House of Lords and several subsections and new clauses were added. Among the additions are a provision that the judicial authority shall in his report to the Commissioners state definitely whether in his opinion the detention is or is not proper, and another to the effect that the power of two or more local authorities to agree to unite in providing and maintaining a district asylum shall be construed as including a power to unite in providing and maintaining a laboratory for pathological research in connexion with lunacy.

The Cost of the Medical Establishment of the Army.

The effects of the war are visible in almost every item of the estimates for the medical establishment of the army. The total vote for 1899–1900 was £305 800, whereas for 1900–1901 it is no less than £555,000. Under the head of pay, &c., of the Army Medical Service there is an increase of £41,800; of pay of civilian medical practitioners, &c., an increase of £120,600, the figures being £134,500 as against £13,900; of corps pay and extra duty pay of the Royal Army Medical Corps, nurses, clerks, and other subordinates, an increase of £36,300; and of cost of medicines, &c., an increase of £50,000. In his explanatory statement the Secretary of State said that all the available officers of the Royal Army Medical Corps ordinarily on the home establishment had been sent to South Africa and their places at home had been filled by the employment of retired officers and civil medical practitioners. In addition 223 civil surgeons had been sent to the seat of war. Provision, it was further said, had been made for a large increase of officers of the Royal Army Medical Corps, and a further addition had been made to the establishment of non-commissioned officers and men.

HOUSE OF COMMONS.

Thursday, March 1st.

Small-pox Precautions.

Mr. Tatton Egerton asked the President of the Local Government Board whether his attention had been called to two cases of small-pox in London which had been distinctly traced to neglect of due precautions by the authorities at Hull, and what steps he intended to take in the matter to prevent similar cases of outbreak of small-pox.—Mr. Chaplin: I have made inquiries with regard to this matter. It appears that the two men from whom the cases referred to are thought to have derived the infection were employed by a contractor in erecting additional buildings at the small pox hospital at Hull. I am informed that it was desired by the Hull authorities that the men employed should be revaccinated before entering on this work. It was also arranged that the men should not be required to work within 60 feet of any building in which there were small-pox patients, but there is some conflict of testimony as to whether this arrangement was strictly observed. The only effective precaution that can be taken in cases of this kind is revaccination, and in the present instance gratuitous revaccination was offered to the men but unfortunately they declined to accept the offer.

The Meat on Board the Transports.

Mr. Baird asked the Financial Secretary to the Admiralty (1) whether any reports had been received from officers commanding troops on board transports for South Africa on the quality of meat supplied to the troops; (2) whether on several occasions the meat had been condemned by the medical officer and thrown overboard in bulk, while that actually cooked had been found to be uneatable and had been treated in the same way; (3) whether any reports had been received from South Africa on the condition of some of the troops when landed to the effect that they had evidently been underfed on the voyage; and (4) whether steps had been taken to secure that the meat issued to the troops on board transports shall be of good quality and the provisions on sale cheap and plentiful.—Mr. Macartney: Reports have been received from officers commanding troops on board 60 transports victualled by the Admiralty. On seven transports the salt-meat ration was condemned on different occasions and other rations were issued. Five commanding officers have reported that the troops disliked the salt beef rations because they were either too salt, or hard, or unpalatable. The answer to the third paragraph is in the negative. Every care has been taken to secure that the rations issued to the troops should be of the best quality, and in a few cases where complaints had been made that the prices of the canteen were high and the stock of articles sold there insufficient the attention of the owners has been called to these matters and they have been rectified. I may add that in the case of every ship where complaints were made the salt beef has been landed at the Cape and that the report of the board which has surveyed it is to the effect that it is quite satisfactory.—Sir James Fergusson: Is it not the fact that in some of the transports the cases of salt beef were marked "1893"?—Mr. Macartney: No, sir, I have not had any report to that effect and I do not believe there is any foundation for the statement.—Sir James Fergusson: I will give you proof.

Friday, March 2nd.

Proposed Special Night Staff for Netley Hospital.

Captain Norton asked the Under-Secretary of State for War whether, seeing that non-commissioned officers and men of the Royal Army Medical Corps are on duty for long hours in attendance upon sick and wounded at the Royal Victoria Hospital, Netley, he would consider the advisability of organising a special staff of night orderlies, who would be excused day duty as in all large civil hospitals, in order that the sick or wounded might be at least as well attended to as the civilian patient.—Mr. Powell Williams: The question has been very carefully considered and in view of the number of experienced men of the Medical Staff Corps who have applied to re-enlist and by whose help the pressure will be greatly diminished it is not thought expedient to form the special staff suggested.

The Meat on Board the Transports.

Sir James Fergusson asked the Financial Secretary to the Admiralty whether he had inquired into his statement that cases of salt beef marked "1893" were shipped for the rations of troops going to South Africa.—Mr. Macartney: 1842 pounds of beef of the date "1893" have been returned from the *Kildonan Castle*. I must therefore apologise to my right hon. friend for making a statement on the subject which was not correct. No beef of that date was supplied to any other transport from which complaints have been received. I made inquiries on that point by telegraph yesterday. The complaint that the beef was hard as regards the *Kildonan Castle* did not come from the commanding officer of the *Kildonan Castle*.

Monday, March 5th.

Proposed Food Standards.

Mr. Hedderwick asked the President of the Board of Agriculture whether any and what steps had been taken by the Board of Agriculture in exercise of the power conferred by Section 4 of the Sale of Food and Drugs Act, 1899, upon the Board, to set up presumptive standards of quality in respect of milk, cream, butter, and cheese.—Mr. Walter Long: No regulations under the section referred to have as yet been made, but I have appointed a Departmental Committee, of which Lord Wenlock is chairman, to consider whether any such regulation can with advantage be made in respect of milk and cream, and upon the report of the committee the further action to be taken will to a great extent depend.

Tuesday, March 6th.

The Nursing Staff of the new Bethnal-green Infirmary.

Sir Mancherjee Bhownaggree asked the President of the Local Government Board whether the Board of Guardians of St. Matthew's, Bethnal-green, applied some months ago for sanction for the appointment and salaries of the nursing staff for the new Bethnal-green Infirmary, and that, although that institution was completed and ready to receive patients, and was formally opened yesterday, the sanction has not been accorded; and, if so, would he take immediate steps to comply with the request of the guardians.—Mr. Chaplin. The Local Government Board have received the application referred to and there has been considerable correspondence on the subject. The Board's decision in the matter has been communicated to the guardians. They have sanctioned the number of nurses required, and I hope that the matter may now be regarded as settled.

Workhouse Dietary Scales.

Mr. Chaplin, replying to a question by Mr. Hazell, said he was sorry there had been delay in the issue of the regulations with regard to workhouse dietaries. The delay had been mainly caused by the great care which had been requisite in framing the model dietary scales which the Committee on the subject recommended should be issued. He was unable to name a date when the regulations would be ready, but they were being pressed forward and there would be no avoidable delay in their issue.

The Inspection of Cows and Dairies.

In their Bill now before the House of Commons the Corporation of Taunton seek power to inspect cows and dairies outside the limits of the borough, a power already enjoyed by other urban local authorities. After the Bill had been read a second time Mr. Strachey moved an instruction to the committee by whom the measure will have to be considered to provide that this power shall not be exercised without the previous order of two justices sitting in petty sessions who shall not grant the order unless they are satisfied that the local authority of the district in which the premises are situated has not a ready dealt with the case.—Sir Walter Foster and other members opposed this instruction on the ground that its effect would be to hamper the corporation in its public health work and on a division it was rejected by 63 votes.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Guest.—On Feb 17th, at Dorrington, Salop, the wife of Herbert M. Guest, L R C P Lond, M.R.C.S., of a son.

Hinds.—On March 1st, at The Steyne, Worthing, the wife of Frank Hinds, M.D, *of a son.*

Hooley.—On March 4th, at Broxmore, Cobham, Surrey, the wife of Arthur Hooley, L.R.C P. Edin., M.R.C.S., of a daughter.

MARRIAGE.

Pakes—Fisher.—On March 1st, at St. Andrew's, Fulham, by the Rev. Charles Pakes, B A., Vicar of Copp, Garstang, father of the bridegroom, assisted by the Rev. J. S. Skinner, B.A., brother-in-law of the bride, Walter Charles Cross Pakes, L R C.P., D.P.H., to Dora Agnes, youngest daughter of the late John Fisher, Esq., of Leckonby, Gt. Eccleston, Lancs.

DEATHS.

Guy.—On March 2nd, at Shoebury Villa, Dover, Thomas Guy, M.D., F R.C P., Inspector-General of Army Hospitals, retired, in his 81st year.

Heron Watson.—On Feb. 27th, at Gotha, Germany, Elizabeth Gordon Miller, wife of Patrick Heron Watson, LL D., M.D., F.R.S., F.R.C S.E. & I., Surgeon-in-Ordinary to the Queen in Scotland, and daughter of the late James Miller, F.R S., F.R.C.S, Professor of Surgery in the University of Edinburgh, and Surgeon-in-Ordinary to the Queen in Scotland.

Simson.—On March 2nd, Francis Taylor Simson, L.R C.P., L.S.A., of Montague place and Craven House, Northumberland-avenue, W., aged 40.

Wearing.—On March 2nd, at Mayfield, Victoria Park, Wavertree, Liverpool, Richard Wearing, M.D., aged 46 years.

Whistler.—On Feb 27th, at his residence, 6B, Bickenhall-mansions, Gloucester-place, London, William McNeill Whistler, M.D. Pennsyl., M R.C P. Lond, M.R.C.S. Eng., late Surgeon to the Confederate States Army, U.S.A., aged 63. (American papers please copy.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE BRITISH VIAVI COMPANY.

On Feb. 27th the coroner for East Sussex opened an inquiry into the circumstances attending the death of Elizabeth Mary Lake, aged 42 years, who died on Feb 25th. Mr. Percy Lake, the husband of the deceased, said that his wife had had no medical attendance, but had been to see Miss O'Dowda until within a *few days of her death,* when Miss O'Dowda had come to the house by his request. In reply to the coroner witness said that Miss O'Dowda was the agent to the British Viavi Company. His wife had adopted the Viavi treatment in March last year. Miss O'Dowda, examined by the coroner, is either in reality, or poses as, an ignorant woman. She said that she was a branch house manager for the British Viavi Company. Asked "what is the Viavi Company"? she said that she did not understand the question. Further pressed she said it was a company for health treatment at home Her business was to give instructions with regard to the remedies to people who wished to buy them, to advise them as to their application, and to put them in touch with the hygienic department in London, which was controlled by a medical adviser, where they are treated by correspondence from London. She did not give medical advice but only instructions as to the application of the remedies. Mrs Lake had described her symptoms and witness considered that she was suffering from a "tumorous condition of the bowels," and therefore advised the use of the medicine recommended by the company for that complaint. The medicines were composed of vegetable substances, but she did not know what they were. The price of the ointment, tablets, bottle of liquid, and capsules was 36s.—that is to say, that for each preparation the sum of 36s. was charged. Witness had no medical qualification and had no idea that deceased was going to die. Witness had been trained as a Viavi worker under Miss Glassford. She had offered no objection when Mr. Lake wished to call in a medical man. They worked hand-in-hand with all medical men. They sent for one when necessary. In answer to the coroner, however, Miss O'Dowda confessed that when they had sent for a medical man he would not work with them.—Dr. Alexander Harper, a registered medical practitioner who had been called in at the end and who had found Mrs. Lake dead on his arrival said that he had made a post-mortem examination. The cause o death was perforation of an ulcer high up in the small intestine. He did not think that a diagnosis of its existence could have been made with certainty during life even by a qualified medical man, but its existence would certainly have been suspected. It was probable that the ulcer had existed in March, 1899, when Miss O'Dowda first saw the deceased. Henry Thomas Woodward, describing himself as M D. of the University of Pennsylvania, said that he was connected with the company in the hygiene department in London. His business was to look over the correspondence from patients and to return answers. Asked by the coroner if he had any objection to telling the court the ingredients of the medicines witness replied that he had no objection but that he did not know. The coroner in his summing up pointed out that Dr. Harper had stated that the complaint from which the deceased had suffered would possibly not have been diagnosed by a skilled medical man Therefore he did not think that they could say that death was accelerated by incompetence on the part of Miss O'Dowda. The jury handed in the following verdict: "We wish to return a verdict of 'Death from natural causes.' We also think that the life of the deceased might have been prolonged had she been placed under properly qualified medical treatment, and from the evidence brought before us we consider the Viavi Company a fraud."

There is nothing to quarrel with in this verdict. There is no law and there never can be one which will prevent persons tampering with their own health by drugging themselves with nostrums which they buy on the faith of harrowing tales inserted as advertisements, or by dealing with quacks, as was the case of Mrs Lake. Here is a commercial company employing a "medical" adviser who admits *his* complete ignorance of the composition of the drugs on which he advises, and employing an agent who also confesses her ignorance. We have seen from time to time the literature sent out by the British Viavi Company, and as a matter of course it appeals largely to that unhappy class of persons who are always imagining that something is wrong with their sexual apparatus. The company practises quackery of the worst description, and a coroner's jury have said that they consider the company a fraud. The case is one more argument for some measures to be taken for the suppression of quackery.

Our readers may notice that the "medical" adviser of the company styled himself an M.D. of the University of Pennsylvania. This university, whose seat is in Philadelphia, has a good record for work extending over 135 years and must not be confounded with the fraudulent Philadelphia University. If "Dr." H. T. Woodward really graduated in the University of Pennsylvania we trust that his *alma mater* will take notice of his proceedings.

MEDICAL CERTIFICATES FOR THE USE OF THE SCHOOL BOARDS

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 3rd I read a note on the London School Board and Medical Certificates. I have had some trouble with the School Board here on the same subject and have successfully combated their inspectors. I have always refused to give any kind of certificate unless the board would pay fees for them. This of course, they would not do. I therefore told parents of children not to send them to school but to tell the inspectors that if they summoned them I should go and give evidence. This stopped the trouble for a time but at last, after some preliminary nibbling in the shape of threats and abuse of the parents, they issued a summons. I attended and gave evidence and the case was dismissed. They soon summoned another case, thinking to tire me of attendance at the police-court. On this occasion I refrained from attending, but sent a note explaining the circumstances to the chairman of the bench. The plan answered here where we all know one another, but probably would not be sufficient in London. I have had no further trouble in the matter. If I hear any complaints of abuse of parents I send my compliments to the inspector inviting him to issue a summons as he knows perfectly well what my action will be in that case. I may add that largely in consequence of this action by myself and another member of our infirmary staff the School Board have appointed a medical officer with whom our relations are perfectly satisfactory.

I am, Sirs, yours faithfully,

Friar Gate, Derby, March 5th, 1900. G. H. MILNES, M.D. Cantab.

"A CASE OF INTRACTABLE ULCER."

To the Editors of THE LANCET.

SIRS,—In answer to "Tibia" in THE LANCET of March 3rd, the following case may be of interest. A woman, aged 60 years, of feeble health and addicted to alcohol, suffered for 14 years from a large deep ulcer on the inner side of the tibia. It was surrounded by discoloured skin but no varicose veins were apparent. Strapping, rest, mercury, and iodide of potassium only made matters worse, but on the administration of quinine and digitalis the ulcer rapidly improved and within one month was completely healed. The administration of arterial tonics, such as digitalis, in cases of feeble habit and poor circulation is most important and is often attended by surprising results in ulcers, varicose veins, and dermatitis hæmostatica.

I am, Sirs, yours faithfully,

March 6th, 1900. TONIC.

THE DOOR PLATE OF AN OLD MEMBER OF A FIRM

To the Editors of THE LANCET.

SIRS,—Will you kindly give me advice on the following circumstances? An old practitioner called A died over three years ago; his widow sold the practice, left the town, and has no further interest in it except the rent of the house in which A had lived. The practice was bought by B, who after a short time sold it to C, and C has now taken a partner, D. Three years before A's death, A 2 (same name), who was working with him, commenced to practise independently, and is still in practice in the town. C and D still retain A's name on their door-plate, to the annoyance of A 2, who is the only person of that name in the town. Can A 2 compel C and D to discontinue the use of his name?

I am, Sirs, yours faithfully,

March 5th, 1900. A 2.

*** As A has been dead three years and as A 2 has resided six years in the town we think A's name might be removed from the door belonging to C and D.—ED. L.

A METHOD OF TREATING VESICO-VAGINAL FISTULA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET there was published, I believe, some years ago, the description of an operation for vesico-vaginal fistula, in which operation one or two silk threads are brought out of the urethra. I cannot find a reference to it in Neale's Digest, perhaps because my copy is not the latest edition. Can any of your readers tell me where the article appeared, whether in THE LANCET or elsewhere, and if they have any experience of this operation? It seemed to me that, in the hands of a not very expert or experienced operator, the good result was more certain than by the other methods.

I am, Sirs, yours faithfully,

J. DICKSON HUNTER, M.D. Edin., &c.

Arequipa, Peru, Jan. 26th, 1900.

WHO SHOULD PAY?

To the Editors of THE LANCET.

SIRS,—About 12 months ago I was called to a man who was injured underground. He was working in an old working that had not been used for many years making an air way when a stone fell on his leg, breaking it. The fracture was comminuted. Those who went to his aid had a good deal of difficulty in getting to him and in getting him out. He had to pull himself up by his hands and elbows through some narrow parts, for the place had closed in so that there was barely room to crawl. The colliers who went to get him out say it was a most dangerous place. I sent a bill for medical attendance upon him for £15 15s. to the company he was working for. They refused to pay it, as they said it had nothing to do with them. They have no medical man for their workmen, but they only employ a very few. They paid the injured man compensation, 13s., but of course he could not pay my bill, as he could not work for 12 months. He could never have got out of the mine without having his leg attended to, and medical attention probably saved the company a good many pounds, for without it he would have had to have his leg amputated.

I am, Sirs, yours faithfully,

March 5th, 1900. T. W. B.

*** The company, it seems to us, should recognise the claim of the medical man, but we do not suppose they can be legally compelled to do so. Our correspondent should consult a solicitor.—ED. L.

PUBLIC FREE LIBRARIES AND HYGIENE

A LETTER under the above heading appears in the *Greenock Telegraph* of March 3rd calling attention to the dangers in the way of disseminating infection which may arise from public libraries. The writer points out that special danger exists from the practice indulged in by some readers of spitting on their fingers before turning over the leaves. It is quite possible that a book might be infected with the bacillus of tubercle in this way, but the great danger arises from books being taken home to all sorts of places where they may come in contact with children suffering from measles, if not diphtheria or scarlet fever. We believe the subject has not escaped the notice of sanitary authorities, but books are difficult things to disinfect and the application of stringent rules for disinfection each time that a book was returned would be almost incompatible with the continued existence of the library. But as we said in THE LANCET of May 4th, 1889, p. 902, books that are known to have been exposed to the taint of disease should be disinfected and any further issue to the houses of those infected should be temporarily restricted.

"THE CLERGYMAN AND THE MEDICAL MAN."

WITH reference to the paragraphs under this heading which appeared in THE LANCET of Feb. 17th (p. 509) and March 3rd (p. 667), a correspondent using the pseudonym of "Ajax" writes:—"The idea that two tablespoonfuls go to one ounce is still held by you, but I think that if you try you can easily pour one ounce into an ordinary tablespoon. I have found that most people and some practitioners are not aware of this. Of course, this has no reference to the dose of carbolic acid."

THE TRANSVAAL BOERS: WHO AND WHAT THEY ARE

"TRAVELLER" writes to us a long letter upon the above subject. We have not space for all his remarks, but we print the salient passages. "Having noticed in the papers lately the loose application of the terms Afrikander, Boers, and Dutch to our antagonists at the Cape I venture to surmise that their use has become too indiscriminate all round. The term 'Afrikander' was generally used to signify Dutch, French, or English born, bred, and resident in the Cape Colony proper. The term 'Boer' is generally used to designate people born and resident in the Transvaal or Orange Free State before the former was created from the latter. The two terms and peoples have now become entirely differentiated owing to the Boers beyond the Vaal River consisting of a mixed nationality of Dutch, French, Germans, Hebrews, Austrians, &c. The real Dutch of the Cape Colony proper were pre-eminently careful of family connexion and conservative of family history—attributes not yet belonging to the Boer communities of the present day in the Transvaal. The modern Boer has gradually developed into a new race of people of different pursuits, character, and nature from the old Dutch colonists of the Cape of 200 years ago. This speciality may be readily noticed by looking at the old Dutch figures in the pictures of Rubens, Teniers, or Van Eyck, &c., and the sketches of the Boer of the day in the illustrated papers. The Boer is now taller than the old stock—lanky, bony, and of austere visage, and a good horseman, whereas the old Dutchmen were square in figure, fleshy, rubicund in visage, and were good sailors and seamen."

THE FRIEND OF HUMANITY.

IN a newspaper appears the following modest advertisement:—

> "To the Deaf.—A gentleman who cured himself of deafness and noises in head after 14 years' suffering will gladly send full particulars of remedy on receipt of stamped addressed envelope."—*J. Clifton, 12, Norfolk-street, Strand, London.*"

We can find no one in the Post Office Directory named J. Clifton at 12, Norfolk street (Amberley House), Strand, but there is a person named Herbert Clifton at this address who deals in "Invisible Drum Supports." He also publishes pamphlets written in the most nauseous style of puffery running down his brother quacks. From this we learn that he has been deaf himself and knows the gloom that was in consequence cast over his life; he has been to these so-called specialists and suffered physically and financially from their nostrums and their charges; he has studied the physiology of the seat of his complaint, and, after patient study and experiment, submitted himself to a course of treatment which resulted in restoring to him once more the blessed power of hearing. He has also determined to give to the world the benefit of the extensive studies and experiments which enabled him to succeed where so many others failed. Mr. Clifton evidently had a bad time. As a lad he suffered from noises in the head and his life became a burden (in large capitals). Nearly a dozen different surgeons saw him and "I realised the awful truth that deafness was certainly creeping upon me" (small capitals). Then he tried the various "quack remedies which have allured so many to their bitter cost." Then a wild yet happy thought flashed upon him and after patient research he mastered the intricacies of those important structures situated in the head and known as the "middle-ear" and "inner ear." Mr. Clifton wisely *remarks that there is no need to give the* technicalities of the subject in detail. We say *wisely* because a few lines further on he says that he commenced experimenting to find out the exact combinations of medicines to penetrate the "inner ear" and to restore the little muscles ("ossicles") to their natural state. A man who calls a muscle an ossicle has not profited much by "patient research."

THE TROUBLES OF A PUBLIC VACCINATOR.

AT the annual dinner of the Bolton Poor-law Officers' Association on Feb. 20th a song entitled "The Public Vaccinator" setting forth the trials of those officials under the new Act was sung. The words were written by Dr. John Johnston and give a vivid picture of the troubles of the post. Three of the stanzas run as follows:—

"The announcement that he only vaccinated 'from the calf'
Would sometimes the occasion be of merriment and chaff.
One woman would declare the thought of vaccination shocked her,
While another one would tell him she preferred the 'Sixpenny Doctor.'

"When asked—'Heaw mony marks d'ye make?'—and he confessed to 'four,'
The mother oft with promptitude would show him to the door;
'The vaccination's free,' he'd urge, 'with lymph of the L G.B.,'
'Aw'st ha' *nowt at a' to do,' she'd snap, 'wi' oather it or thee.'*

"Postponement would another urge, ''cos th' chilt's noan raley fit.'
He'd call again to find it done by 'Sixpenny' or 'flit.'
Another would deny herself, and in no dulcet tones,
Declare he'd made a great mistake—*she* wasn't Mrs. Jones."

POPULAR MEDICINE.

WE have received a copy of *Leach's Family Dressmaker* for February. The journal is published monthly and its circulation is, we believe, a large one. The proprietors think it right to insert medical advice, obviously given without the prescriber seeing the patient, as well as objectionable advertisements. Some of the latter, as will be seen, are disgraceful. On p. 12 we find the following answer to a question by a correspondent who gives the eminently appropriate *nom de plume* of "Stupid": "Try equal parts of lemon juice and lime water to the patches and if not eradicated in a few weeks send 2*s*. 6*d*. for the preparation for bleaching moles which leaves no scar." "Editress," who answers "Stupid," warns her against using "acetic acid, which requires great care in applying through a small glass tube." We, for our part, warn "Stupid" against the half crown preparation, and generally against applying to popular papers for advice about her complexion. But certain advertisements in *Leach's Family Dressmaker* require serious comment. We note the advertisement on p. 25 of "Martin's Apiol and Steel Pills (for ladies)—a French remedy for all irregularities." On the same page Mr. Towle says of his pennyroyal and steel pills for females that they quickly correct "all irregularities, remove all obstructions, and relieve the distressing symptoms so prevalent with the sex." Also, on the same page, is an advertisement from a lady dwelling at 10, Bookseller's-row, Strand, W.C., who gives away "words of wisdom for our wives." The advertiser will also send post free illustrated lists of rubber appliances, preventatives, &c. The worst advertisement is that upon p. 23. It is dated from 145, Stockwell-road, London, S.W. Applications are to be addressed to Mrs. F. D. This is the address from which Mrs. B. B. F. Allen, Mrs. M., Owen, or the Irristum Company, were wont to issue their circulars. In THE LANCET of Dec. 24th, 1898, p. 1723, we commented upon the advertisements of this protean person, and as we notice that "Mrs. W." now expresses to Mrs. F. D. her relief that "her anxiety and misery was over" that she formerly expressed to Mrs. Allen and the others, we conclude that Mrs. F. D. is a fourth name for this firm. Mrs. W.'s testimonial implies that she had a miscarriage and the advertisement is, as the jury found in Owen *v*. Greenberg, immoral. There is another advertisement of a very shady type upon p. 3 of the cover. It relates to "not a dangerous drug, but a wonderful secret invention, never fails." This is addressed "To Married Ladies." With reference to the advertisement of Mrs. F. D. we would direct the attention of the proprietor of Leach's publications to Mr. Justice Darling's dictum in the "Madame Frain" trial "that the newspapers who put in advertisements of this kind now had a warning and that if they continued to do so they might find themselves in the same position as the defendants who were here."

INTERROGATOR would like to hear of a home (private) where a mentally deficient girl, aged 19 years, could be received and not only educated but taught an occupation.

Assistant.—1. Unless the matter is dealt with specifically in the agreement it is one that must be mutually arranged between the principal and assistant. There can be no actual right or wrong about it. 2. The work detailed seems to us enormous for one man to do, but if the assistant has agreed to do it and cannot allege that he has been deceived in any way as to the amount to be done, we can only advise him to do his best. 3. To break a signed agreement would be a serious course which we could not take upon ourselves to recommend. Our correspondent should consult his solicitor.

A.M.C. is advised to consult about the book those who superintended her training. No offers would be made for the papers in question which only have value when the issues are old and out of print.

C. T.—We do not print the addresses of medical men. They can be found in the Medical Register and Medical Directory.

W. S.—The spraying of the throat with local disinfectants has been tried. The results are not conclusive.

Dr. J. Dysart McCaw.—We have received over 1000 letters on the subject. All will have consideration.

W. G. is thanked for bringing the amusing passage to our notice.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, W C)—3.30 P M Dr R Russell Cerebellar Localisation

WEDNESDAY (14th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P M Prof C Stewart: On the Protection and Nourishment of the Young in Plants and Animals.

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—5 P M Dr R. Saundby: Clinical Lecture:—Non-diabetic Glycosuria.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton)—4 P M Mr Godlee: On some peculiar Cases of Empyema.

THE SANITARY INSTITUTE, (Parkes Museum, Margaret-street, W).—8 P M Discussion on Experimental Bacterial Treatment of the London Sewage (to be opened by Prof Frank Clowes)

THURSDAY (15th).—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P M Dr F J Waldo: Summer Diarrhœa with special relation to Causation and Prevention (Milroy Lecture)

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck street, W)—5 P M Clinical Demonstration:—Dr T D Savill: Electricity in the Diagnosis and Treatment of Diseases of the Nervous System

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W C)—4 P M Dr Colman: Demonstration of Selected Cases

CHARING CROSS HOSPITAL.—4 P M. Dr. Hunter: Pathological Demonstration (Post-graduate Course.)

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—3 P M. Dr H Low: Class. Roentgen Rays. Demonstration II 4 P M Mr J Hutchinson: Consultation (Surgical.)

FRIDAY (16th).—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P M Prof C Stewart: On the Protection and Nourishment of the Young in Plants and Animals.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—4 P M. Dr R. Tilley: Consultation (Eye, Ear, Nose and Throat.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol II of 1899, which was completed with the issue of Dec 30th, and the Title page to the Volume, were given in THE LANCET of Jan 6th

VOLUMES AND CASES

VOLUMES for the second half of the year 1899 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s* by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Mons. F. Alcan, Paris; Aston Union, Clerk of; Advertisers' Agency, Lond.; Aberdeen Royal Asylum, Secretary of; Messrs. Armour and Co., Lond.; *Archives Provinciales de Médecine*, Paris, Editor of; *Archiv für Dermatologie und Syphilis*, Prague, Editor of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Three Lectures

ON

THE SURGERY OF THE STOMACH.

Delivered in the Theatre of the Royal College of Surgeons of England on March 5th, 7th, and 9th, 1900,

BY A. MAYO ROBSON, F.R.C.S. ENG.,

MEMBER OF THE COUNCIL AND HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE, AND SENIOR SURGEON TO THE LEEDS GENERAL INFIRMARY.

LECTURE II.[1]

Delivered on March 7th.

PERFORATION.

MR. VICE-PRESIDENT AND GENTLEMEN,—According to Brinton perforation takes place in from 13 to 15 per cent. of all ulcers of the stomach and according to Habershon in 18 per cent. Seeing that ulcer is more common in women than in men in the proportion of four to one perforation is more frequent in women, but, on the other hand, a greater percentage of ulcers perforate in men. Thus out of 234 cases of death from perforation collected by Brinton 160 were females and 74 were males.

According to Dr. Dreschfeld ulcer perforates on the anterior surface in 88 per cent. of cases, on the posterior surface in only 2 per cent., and at the pylorus in 10 per cent. This is readily explained by the posterior surface becoming so readily adherent to the fixed organs at the back of the abdomen. Perforation is a complication that may occur in any form of ulcer of the stomach, though it is much more frequently found in the simple, round, or acute ulcer than in the chronic form.

All cases of perforation naturally range themselves into two classes, the acute and subacute. In acute perforation there are the signs of a peritoneal catastrophe, usually supervening on the symptoms of gastric ulcer, there being immediate severe collapse with acute pain followed by a rapidly spreading lethal peritonitis. In the greater number of cases of perforation the actual rupture occurs when the stomach is full or moderately distended, and as the rupture usually takes place on the anterior surface the contents are poured into the great sac of the peritoneum, flowing along the depression between the colon and stomach into the right or left lumbar pouch; but if the stomach contents be abundant they flow over the omentum and pass into the pelvis at once. I have operated on cases of recent rupture where, although there were no adhesions, the right kidney pouch only had become soiled, where both kidney pouches only were involved, and where the pelvis and all parts of the peritoneal cavity had become invaded. When an ulcer perforates the posterior surface of the stomach the lesser peritoneal cavity is at once invaded, and if the stomach contents be abundant the fluid pours into the right kidney pouch through the foramen of Winslow and so involves the general peritoneal cavity. Under these circumstances, where there are no limiting adhesions the symptoms are very acute and operation to be successful must be undertaken at the earliest possible moment, as every additional hour increases the risk of failure. If perforation occurs with the stomach empty or only containing a small amount, protective adhesions may be formed in immediate contiguity to the ulcer and recovery may occur; for although the perforation of a gastric ulcer is almost universally fatal we must not forget that in a few exceptional cases the rule does not hold. I have seen two cases of this kind; in one all the symptoms of perforating gastric ulcer were followed by improvement and ultimate complete recovery. In the second there was a clear history of perforating gastric ulcer following on stomach symptoms extending over several years and ultimately demanding operation. I found the anterior surface of the stomach adherent to the abdominal wall which was forming the base of the ulcer. It was quite clear that perforation had occurred at this point, but that adhesions had rapidly formed and prevented an extension of the peritonitis. In two other cases on which I have operated perforation had occurred slowly; in one into the liver and in the other into the pancreas, the inflammation having been limited by adhesions. In perforation following on malignant disease there are the usual symptoms and signs of cancer of the stomach, with the sudden supervention of acute symptoms of perforation.

In subacute perforation there is more difficulty in making a diagnosis as the symptoms are less definite. There may be pain, followed by sickness and faintness, perhaps by vomiting, with slowly extending tenderness of the abdomen and distension; but all these conditions are much less marked in the early stage than they are in the acute variety, though they may at the end of two or three days develop rapidly and end the patient's life in a few hours, or the inflammation may very slowly extend, leading to localised abscess, which tends to extend in various directions. In these cases, perhaps because the perforation has occurred on an empty stomach, there is a small leakage, which becomes more or less encysted by adhesions, and the abscess may perforate into the intestine or on to the surface of the abdomen or into the thorax, or some accidental exertion such as that of vomiting may cause a rupture of the abscess into the general peritoneal cavity. Where the symptoms of perforation assume the subacute form there are many varieties in the combination of signs and symptoms, according to the direction in which the localised inflammatory collection travels. Thus we may have subphrenic abscess on the right or left side, pancreatic abscess, hepatic abscess, retro-peritoneal abscess pointing in various directions, and fistula between the stomach and intestines or between the stomach and gall-bladder, or even on to the parietes. The position of the perforation is responsible for these variations, the peritoneal folds conducting the contents in well-defined directions. In this secondary perforation the course of the pus will be either as in primary perforation of the posterior wall into the small sac of the peritoneum and left subphrenic space, or as in anterior perforation into the great peritoneal sac and the right subphrenic space.

But between these acute and chronic perforations there is a third variety, where perforation occurs and a small amount of fluid escapes, which extravasation is limited by adhesions at some distance from the perforation. For instance, if on the anterior surface the omentum may adhere to the anterior abdominal wall quite across the abdomen and so limit the effusion to the upper region of the abdomen and the right subphrenic space, the lateral extension under the diaphragm being prevented by the falciform ligament of the liver, and the lesser cavity of the peritoneum being protected by adhesions at the foramen of Winslow,—if this variety of subacute perforation occur on the posterior surface the lesser sac and left subphrenic space are alone involved because of adhesions at the foramen of Winslow and because of the falciform ligament limiting extension between the diaphragm and liver towards the front and right side. If the perforation occurs into an adjoining hollow viscus—e g., intestine or gall-bladder—a fistula will be found establishing a communication between the two cavities. Rarely a retro-peritoneal abscess forms, but this is usual only in the subacute or chronic cases where the secondary abscess forms in or near the pancreas and then bursts behind the peritoneum, as in a case on which I operated recently; but this is much less common from perforation of a gastric than of a duodenal ulcer. These clinical and anatomical explanations would seem to account for the varieties one may meet with in perforating gastric ulcer. According to Maydl, one-fifth of all subphrenic abscesses have a gastric origin and of these 95 per cent. are the result of ulcers.

Diagnosis of perforation.—Acute perforation is usually heralded by acute pain with collapse and rigid abdomen, soon followed by distension, retching with ineffectual vomiting, rapid pulse, and lowered temperature. If the patient survive signs of acute peritonitis appear. A peritoneal catastrophe with the previous history of symptoms of ulcer of the stomach and the site of the onset of pain in the superior abdominal region will usually leave little doubt as to the fact of perforation, but it must not be forgotten that other peritoneal catastrophes may simulate perforation of a gastric ulcer and *vice versâ*. A case came under my observation where a perforated gastric ulcer was mistaken at first for a ruptured extra-uterine gestation and another where an extra-uterine gestation was mistaken for a perforating gastric ulcer. The diagnosis can usually be made by a careful physical examination, when there will be found absence of liver dulness owing to free gas passing between the liver and the diaphragm, and if the stomach has been full at the time of rupture or fluid has been given after its occurrence there will be dulness in the flanks and a thrill may be present. If the case be not seen until a later stage the tympanitic distension, owing to peritonitis, replaces the early rigidity of the parietes and the distension may itself give rise to absence of liver dulness. Ineffectual vomiting is suggestive of acute perforation, it being accounted for by the contracting stomach forcing its contents into the peritoneal cavity.

---

[1] Lecture I. was published in THE LANCET of March 10th, 1900.

In the second of the three varieties that I have described, where the perforation may be termed subacute or chronic, the diagnosis may be extremely difficult and at times almost impossible until the case develops. The first symptoms may be acute, subsiding in a little while under treatment, and then again, according to later developments, becoming serious or even acute; or from the onset these cases may be slow and insidious, and the first evidence that perforation has occurred may be the formation of a subphrenic or other abscess. The diagnosis in this case rests mainly on the physical signs in the shape of swelling in the upper abdominal region on the right or left side according to the site of the perforation, and as these abscesses frequently contain free gas the percussion note is often misleading, though the hyper-resonance may usually be readily recognised from a pulmonary sound. Sometimes fluctuation may be felt, at other times the presence of fluid can only be elicited by a thrill on flicking the affected part of the abdomen with the fingers. When the collection of fluid is between the diaphragm and liver the liver may be pushed downwards and the thoracic contents pressed upwards. Here the exploring syringe will afford valuable indications.

The late Mr. Greig Smith drew attention to an important symptom in this class of cases, a line of induration underlying and adherent to, and moving with, the parietes, this being the site at which the omentum is adherent to the abdominal wall, limiting the downward extension of the pus and occurring in subacute perforation on the anterior wall of the stomach. The varieties in symptoms of these subacute and chronic perforations are so numerous that were they entered into minutely the whole of our time would be taken up with the subject. I must therefore leave much that I should like to mention unsaid.

Treatment.—Whatever opinions there may be concerning the treatment of some of the other complications of gastric ulcer, such as hæmorrhage, concerning the treatment of perforation there cannot be two opinions. Surgery, and surgery alone, holds out practically the only hope of cure, and though in the first 100 cases the rate of mortality was something like from 70 to 80 per cent. even in those reported, and must have been still higher if all the failures as well as successes had been chronicled, yet later results show a steadily decreasing mortality. The greater success of recent cases distinctly proves that time is the chief feature. This is well shown in a series of cases, 78 in number, collected by Messrs Keen and Tinker; in cases operated on within 12 hours after perforation the mortality was 28 57 per cent. before 1896, but only 16·66 per cent. after that date, the mean of which is 22 6 per cent In cases operated on from 12 to 24 hours after perforation, the mortality was 50 per cent., and from 24 to 48 hours after 55 55 per cent. An important paper on this subject has been written by Mr. Leonard A. Bidwell.[2] He collected 55 cases of perforated gastric ulcer operated on within the last two years. Of these 33 recovered. An analysis of his table brings out the supreme importance of early operation. Thus all the cases operated on within 12 hours—13 in number—recovered; of the 14 cases operated on between 12 and 24 hours one half recovered, and of the 15 cases operated on after 24 hours only five recovered, which shows the great advantage of early diagnosis and of operating as soon as possible At a meeting of the Clinical Society of London on Dec. 8th, 1899, Mr. Arthur Barker read a paper on 12 cases of perforated gastric ulcer on which he had operated, with the result that five of the patients were saved —equal to 58·3 per cent. mortality. He spoke strongly in favour of sponging in place of flushing the peritoneum. My own experience of acute perforation from the point of view of time is very striking. Of three cases operated on on the second and third day after perforation all died; of three cases operated on at six hours, 13 hours, and 18 hours after rupture all recovered. The following table of 429 cases shows a rate of mortality of 55 per cent.

TABLE VII.—*Statistics of Operations for Perforated Gastric Ulcer (Acute).*

(The cases numbered 9 and 10 are single cases not included in the above statistics.)

The following tables not only serve to show the all-round mortality occurring in operations for acute perforation but also the effect of delay in increasing the death-rate:—

TABLE VIII.—*Weir and Foote's*[3] *Table added to Keen's Table and modified in order to show the Mortality between 24 and 36 Hours (Willmott Evans).*

—	Total cases.	Recovered.	Died.	Percentage of deaths.
Under 12 hours	49	35	14	28 57
From 12 to 24 hours	33	12	21	63 63
" 24 to 36 "	16	2	14	87 5
" 36 to 48 "	2	—	2	100·0
Over 48 hours	33	16	17	51·5
Time not stated	14	4	10	71·3

TABLE IX.—*Analysis of Cases Collected by Mr. Willmott Evans.*

—	Total cases.	Recovered	Died	Percentage of deaths.
Under 12 hours	13	7	6	46·1
From 12 to 24 hours	6	4	2	33 3
" 24 to 36 "	7	4	3	42 8
" 36 to 48 "	3	1	2	66 6
Over 48 hours	3	1	2	66 6

The details of operation in cases of perforation are of great importance. Everything should be done to save shock, for the collapse may, and probably will, be severe. To this end an injection of strychnine should be given, the limbs should be covered with cotton-wool, and the patient placed on a table heated by hot-water bottles or otherwise. While the abdomen is being asepticised plenty of boiling water should be got ready and if possible some cold water that has been boiled. A free incision should be made in the mid-line above the umbilicus; odourless gas will probably escape on opening the peritoneum and possibly some fluid or particles of food. The stomach should then be rapidly and carefully examined, it being borne in mind that the site of perforation is on the anterior wall in 52 per cent., near the lesser curvature in 31 per cent, near the cardiac end in 27 per cent., near the pylorus in 13 per cent., and on the posterior wall in only 8 per cent., so that in all probability the ulcer will be readily found. In my last three cases it was near the lesser curvature on the anterior aspect, and, curiously, in all three it was in exactly the same situation. In the first operation that I performed for perforating gastric ulcer, 16 years ago, the ulcer was most favourably situated about the middle of the anterior wall, but, unfortunately, operation was not performed until the third day after perforation, when there was general peritonitis.

---

[2] American Journal of the Medical Sciences, September, 1899.

[3] Medical News, April 25th, 1896, p. 449.

If the ulcer be not discovered on the anterior wall or near the lesser curvature the lesser cavity of the peritoneum should be explored by tearing a slit in the gastro-colic omentum. Should the lesser cavity be free from fluid or the lining walls be free from injection it is not necessary to proceed further in that direction and the pylorus must then be carefully examined. As soon as the perforation is discovered it must be sutured by apposition of the margins or by turning the edges inward and by inserting a row of Lembert's sutures through the peritoneal coat over the site of perforation and if practicable super-imposing a second row of stitches; but owing to the unhealthy and sometimes indurated condition of the margins of the ulcer this is more easily described than done. If the line of suturing be thought to be insecure, a flap of omentum may easily be brought up and stitched over the opening. This I have successfully done in several cases and as it involves very little time and gives a decided sense of security I think it is not a bad rule to follow in most cases.

Excision of the ulcer is, as a rule, unnecessary and involves a waste of time, but in some cases it may make suturing easier. Having closed the ulcer, the cleansing of the peritoneal cavity must be thoroughly and methodically carried out and if the extravasation of fluids be limited, as in a case that I saw within six hours of rupture and where only the right side of the abdomen was soiled, general irrigation is undesirable and *may do more* harm than good, but the parts should be very carefully wiped by soft sponges, great care being taken to cleanse the various folds and the space between the liver and diaphragm. When the effusion is more extensive and the peritoneal cavity has been generally soiled, irrigation is undoubtedly the best means for cleansing it. I have found a coil of india-rubber tubing with an ordinary abdominal glass drainage-tube fixed to one end of it and a funnel at the other to be more convenient than any more complicated apparatus, and I prefer a normal saline solution at a temperature of 105° F. before any other, though a solution of boro-glyceride or boric acid can be equally well employed. It must be remembered that irrigation should be a means of removing and not diffusing foreign material. It is very desirable, therefore, when gross particles of food are found in the region of the stomach to wipe these away before irrigating. Having done that the glass tube can be pushed down into the various recesses and the fluid allowed to well out. When there is much effusion I usually prefer to make a suprapubic opening and put a drainage-tube into the lowest pelvic peritoneal pouch. As soon as the fluid is returned perfectly clear and when the douche has been applied between the liver and the diaphragm and into every other accessible recess the abdomen may be closed, leaving the pelvic tube for drainage. It does not matter if some of the fluid remains in the cavity so long as it is pure, for it becomes absorbed and acts in the same way as an infusion of saline fluid would do. I am quite aware that some surgeons disagree *in toto* with flushing the peritoneum, preferring always to wipe rather than to flush, but my own feeling is that we should select our cases and where the soiling is limited wipe, but where it is general flush. The most difficult region to purify is that between the liver and diaphragm. When the perforation is on the anterior wall of the stomach the right side of the suspensory ligament is almost certain to be soiled; when it is on the posterior surface the space between the liver and the diaphragm on the left will be soiled. In either cases these regions should be flushed or wiped as the case may be. Lennander has suggested that sterilised gauze should be spread over the upper surface of the liver and that both loins should be drained; his results, however, under this treatment do not seem any better or even so satisfactory as where the ordinary means are employed. Saline infusions, rectal injections, and subcutaneous injections of strychnine may be required to combat shock.

Operation in chronic perforation practically resolves itself into the treatment of peritoneal abscess wherever it may be found; but in case of chronic or subacute perforation from gastric ulcer in by far the greater number of cases the abscess is under the diaphragm. It is curious that an abscess of this kind seldom bursts into the general peritoneal cavity. Maydl, who collected 35 cases, only records two such. Nevertheless, unless surgically treated, these cases nearly always terminate fatally either by extension towards the thorax or from septicæmia or exhaustion.

With regard to the site of operation that will depend entirely on the position of the pus. In case of right subphrenic abscess an incision may usually be made in the superior abdominal region to the right of the middle line. In left subphrenic abscess the pus is behind the liver on the left side of the abdomen and it may be necessary to resect a portion of the eighth or the ninth rib and to incise the diaphragm, care being taken to shut off by sutures the pleura if opened. Or an abscess of this kind, if showing a tendency to come forward, may frequently be drained by an incision from the front through the gastro-colic omentum. Having reached the abscess simple drainage will in most cases be sufficient, especially if a dependent point for drainage can be obtained by pushing a probe from the front and cutting down on it from the loin. If, however, the adhesions surrounding the abscess seem firm, and dependent drainage cannot be conveniently obtained, gentle irrigation of the cavity with boric lotion may be employed by inserting two tubes side by side in the cavity, injecting through one and letting the fluid return through the other, so as to avoid tension which might tend to break down adhesions. As the perforation in the stomach may be still patent, care must be taken not to use any poisonous antiseptic, and for the same reason feeding by the mouth is undesirable, and for some days all food should be administered per rectum so as to give the ulcer time to heal. If the pus be retroperitoneal the abscess may be incised and drained in the loin or it may be possible to reach the pus by an incision to the inner side of the anterior superior iliac spine and then by lifting the peritoneum to open and drain the abscess sac, making a counter-opening in the loin if thought desirable. The tube must be gradually shortened as the pus lessens, and left out as early as is safe, lest a fistula should form.

There are very few published statistics of operations for chronic or subacute perforation of gastric ulcers. Barling[4] collected six cases, in which two patients recovered and four died. Comte[5] brought together 23 cases, in which 11 patients recovered and 12 died; and Van Valgal and Nisbit report 10 operations with three recoveries. The total mortality of these cases was 58 9 per cent.

GASTRIC FISTULA.

Gastric fistula, a sequel of perforation, may be found occasionally on the surface of the abdomen, very rarely in the loin, but not infrequently between the stomach and adjoining organs. It may be pathological or traumatic. The following is an etiological classification:—

Pathological.—Extrinsic.—Cancer of the gall-bladder or bowel; gall-stones; empyema of the gall-bladder; abscess of the liver; abscess of the pancreas; ulcer of the bowel, simple, malignant, or tuberculous; and subphrenic abscess bursting into the stomach. Intrinsic.—Ulcer of the stomach or pylorus; cancer of the stomach or pylorus; foreign bodies ulcerating into neighbouring organs; and subphrenic abscess of gastric origin.

Traumatic.—(*a*) From injury, and (*b*) from operation (gastrostomy and gastro-enterostomy).

The symptoms vary according to the cause and the site of the fistula. If it be between the stomach and upper bowel the symptoms may be slight or absent, but if it be between the stomach and the large bowel the food will pass too rapidly through the alimentary canal and be parted with before absorption is adequate for nutrition, and, on the other hand, gases from the colon entering the stomach will give rise to fœtid eructations, at times to feculent vomiting, and always to chronic dyspepsia. In a case of fistula between the gall-bladder and stomach dependent on gall-stones in a woman of 50 years of age who came under my observation there was great loss of flesh, with frequent vomiting of bile; for though it is known that healthy bile may pass through the stomach without serious harm to nutrition the pathological products from an inflamed gall-bladder, together with the infected bile associated with cholelithiasis, seemed in this case to have a very deleterious effect. After opening the abdomen the fundus of the gall-bladder was found to be firmly fixed to the stomach near the pylorus, and on separating the adhesions both openings into the gall-bladder and stomach were found well within reach. The stomach fistula was closed by two layers of sutures and then the gall-bladder was brought to the surface and a tube inserted for drainage. The patient made a very satisfactory recovery and is now quite well, having gained considerably in weight. In another case of fistula between the liver and pylorus the stenosis caused by the ulcer produced such serious symptoms of itself that it was difficult to estimate the part played by the fistula. In this case also I operated, excising the ulcer and stitching up the wound transversely to the pyloric axis, and then scraping out the cavity in the liver. The patient is now in excellent health. In another case of fistula between the stomach and pancreas there was dyspepsia with pain after food and great loss of flesh, but in this case the stenosis of the pylorus seemed to account for the greater part of the trouble.

---

[4] *Birmingham Medical Review*, 1895.

[5] Semaine Médicale, 1895.

Fistulæ on the surface of the abdomen, if small, may cause little loss of health, but if extensive the leakage from the stomach of food and gastric juice leads to great distress from the soreness of the skin around the fistula, and to loss of flesh from the waste of food.

The following specimens are from the Hunterian Museum:—No. 2531 is a specimen of a cancerous ulcer between the stomach and the colon. The disease probably commenced in the colon. The specimen is from a woman of 55 years of age. Death occurred from exhaustion. There was no vomiting. No. 2426C is a specimen of cancer of the pylorus involving the transverse colon. It is from a woman 39 years of age.

Diagnosis.—As a rule, except in surface fistulæ, diagnosis can only be made after opening the abdomen, but if unaltered or slightly altered food be seen in the fæces after a history pointing to simple or malignant ulceration of the stomach, a fistula between the stomach and the colon would be suspected, especially if fœtid eructations or feculent vomiting occurred from time to time. The inability to distend the stomach with air pumped through an œsophageal tube would help in the diagnosis.

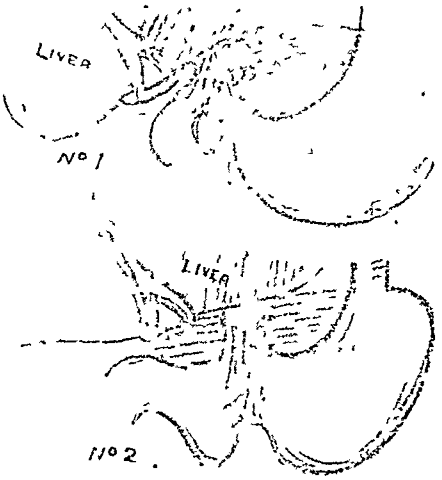
Treatment—In simple internal fistulæ exploration by abdominal section and closure of the two openings may be done, as in the cases previously referred to. In malignant disease partial gastrectomy and enterectomy might possibly be performed if the disease could be discovered in time, but such a communication would probably mean advanced disease and secondary infection, and would, therefore, as a rule, be beyond operative treatment. Surface fistulæ can be closed readily by plastic procedures if they do not close spontaneously under careful dressing and rest. Such a fistula may be closed by carefully dissecting the adherent peritoneum away from the parietes without opening the peritoneal cavity and then invaginating the margins of the opening in the stomach and suturing them accurately together with two layers of superimposed sutures, afterwards closing the muscular and aponeurotic layers of the abdominal wall by separate sutures, and lastly the skin. This operation is sometimes necessary in closing a gastrostomy opening that has been made for temporary use.

PERIGASTRITIS AND ADHESIONS.

Adhesions of the stomach and pylorus to neighbouring organs are a common result of perigastritis, the causes of which may be extrinsic or intrinsic. Among the extrinsic causes are gall stones, tuberculous peritonitis, local peritonitis from intestinal ulceration or from malignant growths in adjoining organs, typhoid fever, and possibly other fevers Among the intrinsic causes ulceration is by far the most frequent, though cancer and syphilis of the stomach must also be included Though at the time adhesions the result of perigastritis are conservative and may frequently result in the saving of [illegible] by limiting peritonitis, the result of perforation [illegible] infection due to ulcer, yet later [illegible] great functional disturbance by [illegible] of bacteri[illegible] such adhesions may lead to interfering with the motor activity of the stomach and causing pain, disability, and other ailments. As I shall hope to show, not only are these disturbances caused by adhesions of a functional nature, producing dyspepsia and so-called visceral neuroses, but not infrequently dilatation of the stomach, vomiting, severe pain, and great loss of flesh may result. In 1893 I read a paper before the Clinical Society of London on the subject of pyloric adhesions and related several cases which had been cured or relieved of long-continued stomach symptoms by their division. Since that time my experience has considerably extended and I can now point to a very large number of cases (nearly 50) of pyloric or other stomach adhesions caused in some cases by gall-stones, in others by gastric ulceration, where the adhesions, though not the original disease, were of the first importance in producing the symptoms for which operation was undertaken and where gastrolysis led to their relief or cure. Though in some cases the adhesions may be due to a perforating ulcer it is by no means necessary that ulceration need be near perforation to lead to perigastritis, for in many cases long before the peritoneum is reached by the ulcer a local peritonitis occurs, leading to the pain and well-known local tenderness which characterise ulcer of the stomach, and then lymph is thrown out which may fix the inflamed region to contiguous organs

Adhesions are found around the stomach in about 5 per cent. of all necropsies, and about 40 per cent. of all cases of ulcer of the stomach are associated with adhesions. My experience in a very considerable number of abdominal sections, about 500 of which have been in the upper abdominal region, is that pyloric adhesions are very much more common than is usually supposed and that their importance is greater than is generally recognised even at the time of operation. This is especially the case in cholelithiasis where I am accustomed to find gastric dilatation as a regular sequence of gall-stones and to look for it as an ordinary concomitant sign; and in such cases it is almost always due to adhesions of the pylorus to the gall-bladder and liver. Sometimes the adhesions may be strictly limited to the pylorus and gall-bladder leading to a characteristic train of symptoms. In one case under my care "acute dilatation" of the stomach came on suddenly and ended fatally within 36 hours, it being apparently due solely to pyloric adhesions, as a post-mortem examination revealed no other cause. At other times they may extend from the pylorus along the lesser curvature of the stomach, fixing the upper border of the stomach firmly to the gall-bladder, cystic duct, and under surface of the liver. When the pylorus is tied up in this abnormal position, not only are the normal movements of the pylorus and stomach interfered with, but the food has

FIG. 2.



No 1 shows kink of the pylorus from adhesions. No 2 shows adhesion of stomach to liver producing hour-glass contraction (For these and other diagrams I am indebted to my friend Dr McGregor Young) to be forced out at a higher level, and when the pylorus is alone fixed a kink forms, as shown in Fig 2, No 1, leading soon to well marked dilatation with flatulence chronic dyspepsia, and loss of flesh Where perigastritis is due to ulceration the adhesions are only found over the site of the ulcer, and if this be at the pylorus a double difficulty is presented, for not only is there fixation of the pylorus at an abnormally high level but the pyloric orifice itself becomes stenosed from the contraction due to the healing of the ulcer If the ulcer happens to be on the anterior wall of the stomach it may lead to hour glass contraction as in two of the cases I shall relate under that heading (Fig 2, No 2) I find that I have operated on 47 cases of stomach disorder where adhesions alone or adhesions associated with some other disease such as gall stones, led to serious dyspepsia or other digestive derangements and where the removal of the adhesions was followed by great relief or cure of the symptoms The symptoms vary according to the site and cause of the disease from mere dyspepsia to serious apepsia, and the brief descriptions of cases in the following table are selected as illustrating the different causes and effects of gastric adhesions

Although cancer is a well recognised cause of perigastritis in every region of the stomach, the symptoms from adhesions are merged in the more serious ailment, it is therefore unnecessary that I should further consider them at this moment, except to say that they seriously add to the difficulty and danger of pylorectomy or partial gastrectomy I think the cases I have mentioned can leave no doubt in the minds of my audience as to the serious effect of pyloric and gastric adhesions, although it is a curious fact that many recognised authorities on stomach diseases barely mention it The remarks that were made by several eminent physicians when I gave my original paper on this subject before the Clinical Society of London showed that although the subject was not unknown its importance was certainly under rated That I am not exaggerating its importance is shown by reports of cases by other observers For instance, Hartmann and Soupault[6] relate cases where adhesions were the only apparent cause of gastric dilatation Terrier, in his work on Stomach Surgery (1899) relates a case of a woman, aged 62 years, whose gastric symptoms were relieved by breaking down adhesions Brieto related a very instructive case, resembling one of mine above described, where a band was

TABLE X —SHOWING THE CAUSES AND EFFECTS OF GASTRIC ADHESIONS

Date	Sex	Age	Operation	Description	Result	After history	With whom seen
Dec 4th, 1895	M	32	Gastrolysis	Ten years previously there was obstruction of the bowels lasting for a week with vomiting and abdominal colic A similar attack occurred a few months later Since then the patient had been subject to bilious vomiting and for two years to dyspepsia and flatulence with constipation but there was no marked jaundice For two years there was pain in the right hypochondrium which was relieved by taking food He never vomited blood There were loss of flesh and increasing debility and well marked tenderness over the gall bladder and the pylorus with dilatation of the stomach Operation The pylorus was found to be tucked up to the liver and kinked, the adhesions round the pylorus were separated No gall stones were present	R	The patient made a good recovery By March 3rd 1896 he had gained a stone in weight. In 1900 he was well and had been engaged in full active work as a medical man in a large practice ever since he recovered from his operation	—
July 6th, 1897	F	36		The patient had had spasms for 20 years Cholecystotomy had been performed 10 months before when four gall stones were removed. After healing of the wound in five weeks there was return of pain There were pain always after food and at times vomiting but never of blood The patient lost flesh rapidly There was dilatation of the stomach but no tenderness over the gall bladder Operation The adhesions between the pylorus and the gall bladder and the liver were broken down and omentum interposed		On July 6th, 1898, the patient wrote: I now feel a different person and enjoy perfect health	—
July 25th, 1899	F	25	"	There had been dyspepsia without vomiting for 16 months and some pain after food Latterly there was pain which was dragging and continuous chiefly in the epigastrium There were loss of flesh and dilated stomach Dieting and rest gave no relief On pelvic examination under ether a small ovarian tumour was found Operation: The pylorus was adherent by a long band to the right anterior abdominal wall The adhesions were separated and ovariotomy for tumour was performed at the same time		The patient was well in February 1900 She has lost all previous troubles and has gained weight	Mr F H Mayo (Headingley)
August 22nd 1899	M	31		The patient had been ill since February, 1893, when he had influenza followed by scarlet fever in March In the same year biliary colic with jaundice and during the year repeated similar seizures At the beginning of 1899 he was jaundiced for six weeks Latterly gastric symptoms were very prominent There were pain and dragging after food and occasionally vomiting He lost 2 st 3 lb in weight in the last 16 months. At the examination rigid right rectus and tenderness below the ninth costal margin were found There was no jaundice but there was dilatation of the stomach Operation Extensive adhesions of the pylorus and pyloric extremity of the stomach to the liver and the gall bladder which was contracted Gastrolysis and cholecystotomy were performed The adhesions were separated and the gall bladder was drained	"	The patient was well in January 1900 He had regained the lost weight	Dr R. Turner (York)
Dec 7th 1899	M	49	"	There had been dyspepsia for two years with progressive loss of weight to the extent of 2 st 2lb within the last year There was no history of ulceration. There was questionable cholecystitis following influenza. At the examination rigid right rectus with little tenderness and a dilated stomach were found The patient was thin but not emaciated Operation: Many small bands fixing the pyloric extremity of the stomach to the gall bladder and causing a kink in the first part of the duodenum The adhesions were separated	"	The patient made a good recovery and gained 1 st in weight within two months	Dr W McGregor Young (Leeds)
Jan 2nd, 1900	F	42	"	Twenty two years before there had been symptoms of ulcer of the stomach Since then the patient had suffered from attacks of vomiting every week or two and from pain after food During the last three years the symptoms had become more marked Under medical treatment, with rest in bed there was no improvement She vomited material large in quantity and fermenting, and sometimes containing blood There had been loss of weight to the extent of 3st and great tenderness over the stomach especially to the left. The stomach was dilated reaching below the umbilicus and well over to the right. Operation On the anterior surface of the stomach there was found the scar of an old ulcer The lesser curvature was closely adherent to the liver The pyloric extremity and first part of duodenum were attached, high up to the gall bladder and cystic duct.	"	The patient made a perfect recovery She can now (March 1900) eat anything without discomfort and is rapidly putting on flesh having gained 19lb in a month	Dr T Holmes (Garstang

---

[6] Revue de Chirurgie, 1899 p 340

found attached to the lesser curvature of the stomach about one and a half inches from the pylorus, which ran obliquely downward to the anterior abdominal wall on the right of the umbilicus. When the stomach was full the band dragged the upper border downwards and produced a kink which led to stenosis. A case related by Mr. H. W. Page[7] is a good example and many others can now be found scattered through medical literature.

The diagnosis in these cases rests on a careful consideration of the previous history, together with the presence of well-marked signs and symptoms, so that it is not generally difficult. There will usually be a history of gall-stones, typhoid fever, ulcer of the pylorus, or some local peritonitis in the pyloric region, months or years previously. This will have been followed by indefinite dyspepsia and flatulence, which later takes a very definite shape, consisting of discomfort and pain after food, especially after a full meal, so that the patient prefers to take several small repasts rather than one large meal. The pain and discomfort are at once relieved by the recumbent posture, so that a necessity to lie down or rest after every meal is suggestive. Relief is frequently found by the wearing of a belt and this is usually discovered by the patient before advice is sought. The pain is often of a dragging character. At times it may be acute, and it is increased or brought on by lifting or reaching, say, to adjust a picture Walking or any active exertion may bring on discomfort and pain; hence active exertion is shunned, and inability to perform ordinary duties is complained of. When dilatation of the stomach is well marked there may be loss of flesh and, vomiting every few days, often in large quantity.

Besides the ordinary signs of dilatation of the stomach and the tenderness between the umbilicus and the ninth costal cartilage, as shown by the rigid right rectus, there is an important physical sign to be obtained by distending the stomach with gas, and that is, the cavity of the stomach is found to extend further to the right and higher than normal. An entire cessation of pain and freedom from dyspeptic troubles if the patient be confined to bed is suggestive, for it will be seen that under these circumstances the higher level of the pylorus is done away with and the recumbent posture prevents the dragging of adhesions; but after all, an exploratory operation is the only way of setting doubt at rest, and if these distressing symptoms have resisted long-continued medical treatment a surgical operation is clearly justifiable, though doubtless in some of the less severe forms careful medical treatment may lead to an amelioration of symptoms and may give such marked relief that an operation will not be called for. Relief may be obtained by advising the patient to take small meals and to avoid bulky and fermentable foods such as potatoes and bread, to rest after meals, and to wear a well-fitting abdominal belt. The natural cure, in some cases where there has been no operation, is probably due to the stretching of adhesions and to their absorption if the exciting cause has fortunately been removed; but in the more severe cases, where the adhesions are almost universal, such a fortunate termination of symptoms is scarcely to be hoped for, and in some cases the adhesions are so extreme that nothing short of gastro-enterostomy can prove of any avail.

I have heard it suggested, what is the use of simply detaching adhesions? Fortunately my experience in this class of cases is sufficient for me to give a very direct answer to this query, for I can point to many cases of cure where men and women formerly invalided by pain and dyspepsia are now leading active and useful lives. Slight adhesions I am accustomed to separate with the fingers, firmer bands I divide between ligatures, going carefully to work until I feel that the pylorus is quite free. Where the omentum is available I usually bring the right border upwards and leave it between the pylorus and the gall-bladder and the liver, so that should any adhesions form again they will be in the shape of a loose mesentery and not binding, like adhesions to fixed organs.

The following table of cases (Table XI.) of gastrolysis shows the operation to be a very safe one, the mortality in 77 operations being only at the rate of 2 5 per cent.

HOUR GLASS CONTRACTION.

Hour-glass contraction is generally considered among the rarer diseases of the stomach, but my recent experience would lead me to believe that it is much more common than is usually thought, for I have operated on no less than six cases within a year. As its name implies, hour-glass contraction is a division of the cavity of the stomach into two compartments, but I am able to show a drawing of one case on which I operated where the cavity was actually divided into three. (Fig. 3, lower drawing.) I am fortunately unable to show you the specimen as the patient is now in robust health after being an invalid for 17 years, but on the table is a specimen of a case of hour-glass contraction in which death occurred from perforation of a pyloric ulcer, and in this case not only was there well-marked hour-glass contraction with two large cavities each having a greater capacity than the normal stomach, but the pylorus was also contracted and would barely admit a No. 10 catheter. (Fig. 3, upper drawing.) I am astonished that I can find so few examples of hour glass stomach in the museums, especially as there are a number of cases on record. I fully expect, however, now that more attention is being drawn to the surgical aspect of stomach diseases, that we shall recognise it much more frequently among gastric ailments. On the table are several well-marked examples from the Hunterian Museum.

King's College Hospital Reports, 1897–93, vol. v., p 127.

The chief cause of hour-glass contraction is cicatricial contraction of a chronic ulcer, as in the cases I am about to relate, but the bi-partite condition of the stomach may also be due to perigastritis and the subsequent contraction of a band of lymph, or to adhesions on the outside of the stomach. It is said at times to be congenital, as in cases described by Mr Hastings Gilford[8] and by Dr. Sievers,[9] but as their cases occurred in women aged 32 and 26 years respectively, and as in both there was ulceration of the stomach which terminated fatally, I am not at all convinced that in either the disease was truly congenital. In many cases no morbid changes are found in the walls of the constricted portion; for instance, in 13 out of 22 cases collected by Hiersch, ulcers, erosions, scars, or thickenings were present though at some distance from the constriction.

Anatomy.—The anatomy of hour-glass contraction is best shown by the diagrams (Fig. 3), but they do not show everything. The constriction may be partly hidden by enormous thickening of the stomach wall and the extreme narrowing of the communication may only be made out after the stomach is opened, as in the case related below. In other cases the hour glass condition is evident the moment the stomach is seen. In all my cases the cicatricial character of the stricture showed the case to be ulceration. The smoothness of the mucous lining of the stricture, I take it, is no proof of the narrowing being congenital in any case, for in nearly all of my patients the mucous membrane covering the communicating channel was smooth, although the puckered peritoneum showed that contraction after ulceration had occurred The site of the stricture varies in position, as might be expected, but in all my cases except one it has been sufficiently to the right to leave the proximal cavity decidedly the larger, in that exception the pylorus was also contracted The cavity between the stricture and the pylorus may vary considerably in size, but is seldom dilated to any great extent unless there is also a narrowing of the pylorus

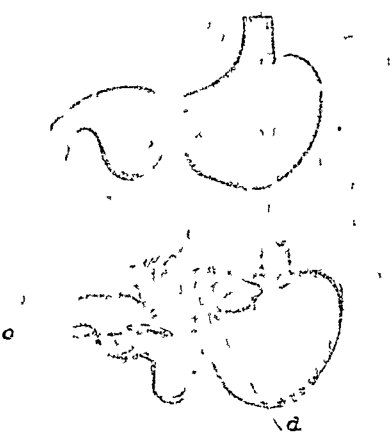
FIG 3



The upper figure represents a bifid stomach and the lower a trifid stomach In the trifid stomach c denotes the opening for pyloroplasty and d an adhesion to the liver

The following are descriptions of the two cases referred to In Mr Hastings Gilford's case a domestic servant aged 32 years, had had symptoms of gastric ulcer since she was 18 years of age She had long periods of dyspepsia nausea, vomiting, pain and bleeding and one or other was never absent There was evidently pyloric obstruction, for enormous quantities of liquid were vomited. There was a regular sequence—comparative ease when she could eat, epigastric pain and anorexia copious vomiting, and relief A very puzzling symptom was observed, an occasional gurgling, very distinct and different from the usual intestinal gurgling She was most comfortable in bed and when she was fed by the rectum When feeding by the mouth was resumed even with fluids pain and vomiting recurred Large doses of bismuth relieved the pain but not the vomiting After three months' treatment without progress, unhealed pyloric ulcer and stenosis were diagnosed and operation was advised A much more complicated condition was found The stomach was bound down by adhesions and it was impossible to explore more than a few inches of its outer surface It was hour glass shaped The stenosis between the two compartments was so complete that the finger could only be forced through with difficulty It seemed impossible for any food to have passed except when the upper cavity was full A third compartment lying between the lesser curvature and the liver was found Probably an ulcer had perforated at this spot and formed an adventitious cavity No active ulcers could be found The stenosis was treated by the method of Heineke and Mikulicz After two days the patient was fed by the mouth —She improved and took slops well but a month after operation severe hæmatemesis set in and she died The external wound was found healed, the gastric wound was unhealed in one part which was apparently the source of hæmorrhage Three very chronic ulcers were present in the dilated first part of the stomach The contraction seemed to be of the nature of a malformation, for no scars or ulcers could be found upon it and it appeared to be too uniform to be due to cicatrisation No doubt the gurgling heard during life was due to the passage of fluid from the accessory cavity In Dr Sievers's case a servant girl, aged 26 years, strong and well nourished, was attacked during menstruation with acute abdominal pain Two days afterwards (on admission into the hospital) the face and extremities were cyanosed and the pulse was 120 weak, and fairly regular The abdomen was distended, tenderness was greatest in the right iliac fossa and the percussion note was tympanitic The patient was extremely thirsty and was exhausted by continual vomiting of offensive dark brown fluid Death rapidly ensued Five weeks previously she had been treated for gastric ulcer and had apparently recovered There had been no other serious illness At the necropsy the abdomen was distended with gas and there was a large amount of foul smelling brown fluid in the peritoneal cavity Several collections of pus were found The stomach was of the hour glass form and there was a perforation large enough to admit the little finger through which the fluid had escaped Either half of the stomach measured about 14 centimetres (five and a half inches) from either the cardiac or pyloric end to the central constriction. The breadth of both cardiac and pyloric portions from the lesser to the greater curvature was about 15 centimetres Uniting the two halves was a tubular connexion about two centimetres long and two and one-third centimetres broad A circular ulcer was situated on the lesser curvature about one centimetre from the constriction, it was one centimetre in diameter Microscopically all the coats of the stomach were normal The other organs were healthy

From the specimens which I here show, which come from the Hunterian Museum, it would seem that cancer must be reckoned among the causes of hour glass contraction The specimen No 2408o was from a man, 60 years of age, who died from asthenia after four years' history of gastric ulcer The cancerous growth is in the anterior wall and might have been secondary to ulcer No 2425, which is from a woman, 50 years of age, shows a cancer of the cardiac end of the stomach partly shutting off the fundus in an hour glass shape so as to form a large pouch As the symptoms had existed for three years this was probably also a case of cancer supervening on ulcer No 2416 is an hour glass stomach with the vessels injected There is a growth round the cardiac end

The following brief notes of three of my cases in private practice illustrate both the symptoms and the beneficial results of operative treatment (See Table XII)

Symptoms and diagnosis —So far as I know very little attempt has been made at diagnosis in this class of cases, but out of my six cases I was able to make a diagnosis before operating in two In all there were stomach symptoms extending over various periods, in one case so long as 23 years, and in every case there was the history of ulceration at the beginning, with gastralgia and hæmatemesis, this being followed by relief for a time and then by relapse and all along by alternate recoveries and relapses, each attack leaving the patient weaker until extreme emaciation with pain and suffering led to the question of surgical treatment Vomiting at first was present during the time of ulceration, then it ceased, to be followed by dyspepsia and afterwards to recur at intervals of several days, in this resembling dilatation of the stomach from stenosis The vomit was hyperacid It contained free hydrochloric acid, and in other respects resembled the fermenting contents of ordinary dilated stomach Constipation with diminution in the quantity of urine excreted was noted among the symptoms Visible peristalsis was seen in three of the cases In all there was marked loss of flesh Borborygmi formed a distinct symptom in several of the cases and were complained of as being a very uncomfortable accompaniment A sulcus between the two halves of the stomach on distension with carbonic acid gas was well marked in two of the cases In these the symptoms were so distinct as to leave no doubt of the diagnosis Two pathognomonic signs were present (1) on cleansing the stomach by lavage and leaving it pure a second washing within a few minutes showed that the distal cavity had emptied itself into the proximal and the second washing out brought away fluid as foul as if no lavage had occurred, and (2) on distending the stomach with air pumped through a stomach tube the two loculi could be distinctly mapped out both by palpation and percussion After all, however, a diagnosis will usually be made by an exploratory incision, and as in other stomach conditions if the distressing symptoms accompanying this condition are associated with marked loss of flesh despite

TABLE XII.—THREE CASES OF HOUR-GLASS CONTRACTION OF THE STOMACH.

Date.	Age.	History.	Operation.	Result.	After history.	With whom seen.
June 6th, 1899.	30	There had been attacks of pain and vomiting for 15 years. The pain began at the left side and passed to the epigastrium and through to the left subscapular region. There was severe hæmatemesis 10 years before. Occasionally before and since the vomit had been streaked with blood, which was sometimes "coffee-ground," but had contained no blood for eight years. The patient vomited large quantities at times and had lost flesh steadily for the last five years. There were dilatation of the stomach and doubtful peristalsis. There was no tumour, but the pylorus was felt to harden from time to time.	Double hour-glass contraction one-third way from cardia, adhesions causing diminution of calibre and two inches from pylorus contraction, only admitting tip of little finger, were found. The adhesions were divided and gastroplasty was performed, the wound being sutured over a large bone bobbin.	R.	On August 6th, 1899, the patient had gained 2 st. in weight.	Dr. W. Duncan (Clay Cross).
July 28th, 1899.	48	The patient had had constant indigestion and flatulence for 20 years with a feeling of pulsation and tenderness. There had been free hæmatemesis two years before and vomiting occasionally since but not regularly. There was pain an hour after food, but lately the patient had ceased to take much solid food. The patient had noticed slime and blood in the motions. There had been great loss of flesh. There was well-marked stomach splash. No tumour was present, but there was tenderness in the epigastrium.	Extreme contraction one-third way from pylorus, just admitted tip of little finger. Gastroplasty was performed, a large bone bobbin being used.	R.	The patient made a good recovery from the operation and the indigestion was relieved. There was an increase in weight to a moderate degree.	Mr. F. T. Hindle (Askern).
Sept. 1st, 1899.	52	In 1873 there had been ulceration of the stomach. The patient had been well for two years, then return of symptoms ensued, the pain now occurring two hours after taking food. Relief followed treatment, but there was recurrence two years later and again in 1885, since which the patient had never been well. The disease was said to have been "nervous" dyspepsia, and the patient was told in 1894 by a physician that she would never be well. For the last nine months she had got rapidly worse, having pain even after drinking liquids and suffering from inability to sleep. There was vomiting about every third day and at times she brought up a large quantity of fermenting fluid. She had lost 2 st. in weight during the last year. Dilatation of the stomach was well marked, but there was doubtful peristalsis. No tumour was found but contraction at the pylorus was felt.	Hour-glass contraction. The communication would admit only a No. 7 catheter. Gastroplasty was performed, a large bone bobbin being employed.	R.	The patient made a good recovery. On Oct. 2nd, 1899, she had gained 5¾ lb., on the 10th 7 lb more, and on Nov. 1st 13¼ lb. additional. In February, 1900, she was reported to be quite well.	Dr. E. Walker (Huddersfield).

medical treatment, an exploratory operation will be amply justified.

Treatment.—With reference to early medical treatment I have not much to say, as in all probability it will be only in the later stages that the surgeon will be asked to give an opinion. Lavage and careful dieting will give relief, but the limit is soon reached if constriction be well marked, and as soon as marked loss of flesh is occurring despite careful medical attention, medical treatment should give place to surgical treatment. After opening the abdomen the stomach must be carefully examined and on the condition found will depend the exact line of treatment to be pursued. If adhesions be the cause of stricture they must be divided, and if after this the communication between the two cavities be sufficiently free the abdomen may be closed. If the stricture be cicatricial its calibre may be easily felt by pinching it up between the finger and thumb, when the lumen will be felt between the finger tips. Three courses are now open: (1) gastroplasty; (2) gastro-gastrostomy; and (3) gastro-enterostomy.

1. Gastroplasty is the operation that I have performed in all my cases and to facilitate its performance I have modified the operation by stitching up the longitudinal incision transversely over a large decalcified bone bobbin, thus making an opening between the two cavities from one and a half to two inches in diameter. Either a catgut suture may be employed for the mucous margin and a silk suture for the serous surfaces or silk sutures may be employed for both. The operation can, of course, be performed by simple sutures without the bobbin, but I prefer to employ the bobbin in order to be sure of having the new opening sufficiently large. Appended is a list of 13 cases of gastroplasty for hour-glass stomach (Table XIII.), in which 11 patients recovered, the two deaths being due to perforation and hæmorrhage which occurred eight days and a month respectively after operation and were dependent on ulceration of the stomach.

2. "Gastro-gastrostomy" seems a good term to apply to the operation for making an artificial opening between the two cavities of the stomach. It can be performed either by simple suture or with the help of a bone bobbin as a splint

or by means of Laplace's forceps, but in this situation I would not advise the use of a metal button as it would have no chance of escaping and might lead to subsequent trouble. Table XIV. shows seven operations, with one death.

3. Gastro enterostomy between the proximal cavity and the jejunum would leave the second cavity with its foul contents untouched, and although relief would be likely to occur I question whether a permanent cure would ensue. If, however, as in my sixth case, it be at once discovered that not only is there a constriction in the stomach, but also one at the pylorus, the question of gastro enterostomy would be worth considering as it would lead to a considerable saving of time by substituting one operation for two. It has been performed by Tricomi successfully.

DILATATION OF THE STOMACH.

Though gastrectasis is by some authors only treated as a symptom it is one of such importance that in many cases it may truly be said to be a disease in itself; this is certainly the case in that serious and often fatal form known as "acute dilatation." A medical friend whose practice lies among mill operatives told me that a moderate degree of dilatation was almost a constant symptom among them owing to their living so much on tea and farinaceous food, and it is generally known that well-marked dilatation is usually seen in gross feeders or in those living almost solely on bulky farinaceous food, such as potatoes. The capacity of the stomach cannot therefore be taken as a guide in estimating the dilatation that should come under the notice of the surgeon and, in fact, it is only in the well-marked cases that a surgical opinion is sought. Unfortunately, the aid of surgery is too frequently put off until extensive emaciation has ensued and the patient is almost moribund.

The causes of dilatation of the stomach are: 1. Mechanical obstruction at the pylorus or near it or in the duodenum, (*a*) from cicatrisation of a simple ulcer at or near the pylorus; (*b*) from cancer of the pylorus; (*c*) from perigastritis leading to stricture or to kink of the pylorus; (*d*) from hypertrophy of the pylorus and spasm as a sequel of ulceration, which may continue long after the original ulcer has disappeared; (*e*) from fibroid thickening of the pylorus; (*f*) from polypus; (*g*) from congenital stenosis; and (*h*) from tumour outside the pylorus. 2. Dilatation from atony from various causes not mechanical, but persisting after the original cause has passed. 3 Acute dilatation from causes not yet understood

Diagnosis.—Although in cases brought before the notice of the surgeon the diagnosis is usually already made he will need to verify its correctness for himself and if possible to arrive at the probable cause. Where there is severe dilatation the stomach soon becomes displaced downwards. This is associated with vomiting, the vomiting differing from that which occurs in any other condition. For instance, it does not occur after meals, nor even every day, but usually every second or third day and more frequently at night than in the day; and when the vomiting occurs it is as a rule in enormous quantity, the vomit consisting of fermented material with mucus, and sarcinæ and yeast cells are usually present. When the dilatation is dependent on ulcer the vomiting may be excessively acid owing to the presence of hydrochloric acid. If, however, the dilatation is dependent on cancer the acidity is due to lactic acid, and hydrochloric acid will be in small quantity or absent. Though patients with dilated stomach do not, as a rule, vomit after food they complain of a sense of heaviness and discomfort and have flatulent eructations, these symptoms becoming more and more intense as the stomach contents accumulate, until relief is obtained by vomiting. As a rule the first sign noticed in stomach dilatation is the splash on succussion of the abdomen, this being the more marked the greater the contents. If the patient has previously vomited, the stomach splash may be absent, but it is usually obtained by allowing him to drink freely of warm water. Constipation and diminished secretion of urine are nearly always present. Where the obstruction is mechanical visible peristalsis from left to right can frequently not only be felt but observed through the abdominal wall; and if visible peristalsis be present it is always indicative of considerable pyloric obstruction which will probably only yield to surgical treatment. Loss of flesh, diminution of body temperature, coldness of the hands and feet, and general feebleness are characteristic of the later stages. Tetany is sometimes present and if well marked may even lead to a fatal termination, but before this stage is reached cramps in the muscles of the forearm and drawing inwards of the thumb, otherwise a tetanoid condition, are usually noticed. The amount of dilatation may be ascertained by distending the stomach with air introduced through a tube and pumped into it by means of a Higginson's syringe. This can be done with very little discomfort and without danger. A simpler method which I frequently employ is to give a dose of tartaric acid immediately after one of carbonate of soda, when if the patient is recumbent, inspection, palpation, and percussion show the increase in size of the organ. As to the cause of dilatation the history materially helps. If it be simple the history is usually a question of years and, if malignant, of months; but in the latter case a tumour is much more frequently present than in the former and an examination of the stomach contents after a test-meal is also of service. In dilatation from ulcer there will usually be a long history of ulceration possibly with vomiting of blood, but it is quite possible for an ulcer of the pylorus to pursue a quiet course and for a long history to be absent. That peculiar form of dilatation known as acute may apparently occur as a result of spasm without organic pyloric obstruction. It is highly probable that nearly every case of extreme dilatation of the stomach has some mechanical explanation and can only be efficiently treated by surgical means. I know that this view is one which will raise some criticism, but I think that time will prove that the statement is correct. I do not, of course, refer to those cases of moderate dilatation which are so commonly seen and which are associated with atonic conditions and with chronic catarrh, but I refer to the cases of dilatation producing the characteristic symptoms I have mentioned. In a discussion with my colleague Dr Barrs I find that he supports these views.

Treatment.—The treatment in any form of gastrectasis will at first be medical and general, but if in a short time weight and strength be not definitely gained and maintained, with relief to pain and discomfort, then time should not be wasted by persisting with lavage and medical treatment for months until the vital powers have become sapped and the patient reduced to the last extremity of exhaustion before surgical treatment is advised.

Surgical treatment.—The stomach should be washed out for a day or two before operation if the patient be not so far advanced that there will be danger in waiting, and during 12 or 24 hours rectal injections may with advantage supplement light stomach feeding. The last lavage should be several hours before operation. A subcutaneous injection of 10 minims of solution of strychnine may with advantage be given just before the operation if the patient be very weak, so as to forestall shock, which may also be further lessened by a pint of saline solution being given by the rectum and by operating on a heated operating table. After exposing the stomach by the incision previously described, a diagnosis of the cause will be speedily made by inspection and palpation of the stomach and pylorus. If there be stricture of the stomach itself, either from cicatrisation or from ulcer leading to hour-glass contraction, it must be treated in one of the ways previously described. If the dilatation be dependent on adhesions of the pylorus and these can be detached leaving the pylorus free, they should be dealt with as I have described.

If there is a stricture of the pylorus it must be dealt with in one of the several ways to be immediately mentioned (pylorodiosis, pyloroplasty, gastro-enterostomy or pylorectomy), according to its nature.

If the narrowing of the pylorus be due to spasm or hypertrophy of the circular muscular fibres, *pylorodiosis* or dilatation of the pylorus may be indicated. This is known as Loreta's operation, since it was he who first employed the method as a definite operative procedure and in 1884 brought it before the profession; but in 1681 Richter dilated the pylorus by bougies and Hahn did the same. Hahn also advocated rapid dilatation through the stomach wall. Loreta practised dilatation of the pylorus through an incision on the stomach side of the pylorus, through which he introduced the index finger of the right and left hand into the pyloric orifice and stretched it forcibly until the diameter was approximately eight centimetres, after which the stomach wound was closed by sutures Bull advocated the use of bougies and Barton used a uterine dilator instead of the fingers. Jaboulay in a case of cancer dilated the pylorus by invaginating the stomach wall by means of a finger, great relief to the patient resulting. This all sounds very simple, and when we hear of Loreta having had 29 cases all successful it would seem that the operation does all that could be desired; but there is another side to the picture when we hear that in the hands of many able surgeons this apparently simple operation has such a high rate of mortality as 40 per cent., and that Loreta himself has confessed to having had several deaths from hæmorrhage and peritonitis. Moreover, recurrence of the stricture seems to have occurred in so large a number of the cases that it is scarcely likely that the operation will hold its own in competition with the more exact and safer operations of pyloroplasty and gastro-enterostomy. It probably has some use in that very limited class of cases where the stenosis is simply dependent on spasm of the sphincter, which may either be caused by ulceration or independently of such a condition. Such a case has been related by Mr. Paul. "The patient was a man, aged 21 years. He was admitted into the Royal Infirmary, Liverpool, under the care of Dr. Caton, in November, 1895, for pain in the epigastric region and a lump. The lump proved to be a largely dilated stomach, in which splashing sounds could be easily produced. He was treated by careful dieting and washing out of the stomach, but not having materially improved in January, 1896, the case was transferred to me. The patient was anæmic, and decidedly of neurotic type. On Jan. 6th the abdomen was opened for exploratory purposes. The stomach was found to be dilated, the pylorus was thick but not fibrous, and upon invaginating the anterior wall upon the forefinger into the pyloric orifice abnormal resistance was met with. This was gradually overcome by continued steady pressure, and ultimately the opening was over-dilated without splitting, by passing three fingers through it. No cut was made in the organ. The patient healed well, but was subsequently attacked with acute mania and had to be sent to the county asylum, where he remained for five months before he got his discharge. He had no recurrence of the gastric symptoms." I have had one case similar to the above in which dilatation was successfully done by invagination. This is, however, the operation suggested by Hahn and not by Loreta. The late Greig Smith held a favourable opinion of Loreta's operation, but Mr. Treves and other surgeons have told me that they have given up pylorodiosis, and my own feeling is decidedly in favour of pyloroplasty where no active ulceration is going on, and of gastro-enterostomy where the pylorus is ulcerated.

The principle of obtaining an increase of the calibre in a stricture by dividing the narrow passage longitudinally and closing the wound transversely (as shown in Fig. 4) is as ingenious as it is efficient, and in no situation can the procedure be of greater service than in simple stricture of the pylorus, when the operation is known as *pyloroplasty*, an operation which is destined to almost replace, if it has not already done so, pylorodiosis. The operation was performed first by Heineke in March, 1886, and his patient recovered. Mikulicz performed his first pyloroplasty in 1887, but the patient died; in his second operation in the same year the patient recovered. Of the first 17 operations 11 recovered. If the pylorus be free from adhesions the operation is of the simplest, as the pylorus can be brought outside the abdomen and surrounded by gauze pads or sponges, so that this heavy mortality of 35·3 per cent. must have been due to an improper selection of cases, as later results only show a mortality of 9 per cent. in Czerny's clinic (Stendel), 7·6 per cent. in my own cases, and no mortality in several series. It is desirable to adopt all the usual precautions against shock, and the stomach should, if practicable, be washed out some little time before operation so as to avoid the danger of soiling the peritoneum. The incision through the pylorus must be longitudinal, commencing on the stomach side of the sphincter and being prolonged through it either by scissors or by the knife over a director. Blunt hooks or catch forceps placed in the wound convert the horizontal incision into a transverse one and it is then closed by a double line of sutures.

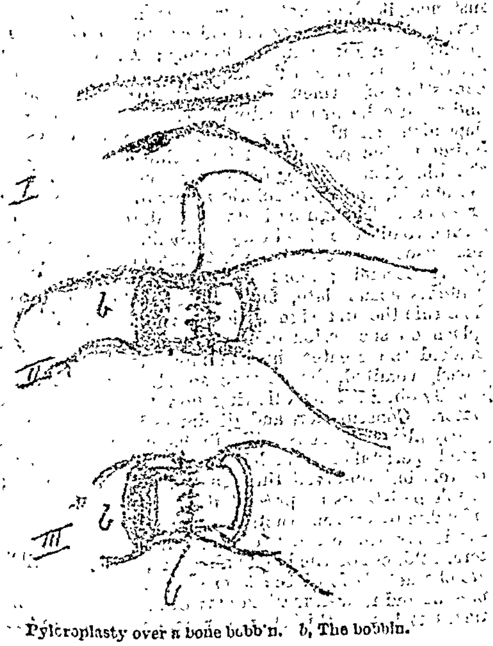
FIG. 4.



Pyloroplasty over a bone bobbin. b, The bobbin.

The modification of the operation by the use of an internal splint in the shape of a bone bobbin over which to apply the sutures is one that I have employed in all my operations and one which I consider offers several advantages For instance, only two continuous sutures are required for the mucous and peritoneal margins respectively The bone tube secures an immediate and thoroughly patent channel It affords protection for from 24 to 48 hours to the line of sutures, by which time union should be established, and it prevents the new channel being inadvertently made too narrow Although the bone bobbin that I originally invented for pylorectomy and enterectomy answers quite well, a recent modification, as shown in Fig 4, in which the barrel of the bobbin is lengthened facilitates the operation This modification has been followed by Rushton Parker[10] and other surgeons with success The following examples are selected from my cases

At the operation cicatricial stricture of the pylorus was discovered. The cure was complete Koeppelin maintains that this modification is safer than the older pyloroplasty The advantage is of course, in the avoidance of opening the stomach cavity and therefore as lessening the danger of sepsis the modification may be occasionally employed, but it should certainly never be performed in the presence of cancer If, owing to the cicatrisation of the ulcer, there be extensive hypertrophy of the pylorus with a large amount of thickening pyloroplasty is insufficient, as in such cases contraction will be likely to recur Here pylorectomy may be performed as in two cases of my own or better still gastro enterostomy, which is a simpler, quicker and safer operation Numerous and firm adhesions, active ulceration, and the presence of new growth, are also contra indications for pyloroplasty

Dr Maurice Richardson[12] advocates partial excision of the stricture where there is extensive thickening and well marked stricture, as in the following reported case in a man, aged 54 years The pylorus was extensively thickened and tightly constricted A longitudinal incision was made for three inches through the stomach, the stricture, and the pylorus The incision was converted into a lozenge shape or a broad V by removing a considerable portion of the cicatrix of the anterior wall of the pylorus By bringing together the opposing surfaces of the duodenum and the stomach an abundant artificial lumen was procured The mucous membrane was first united by a continuous suture, and the peritoneum by an interrupted silk Lembert's suture The patient was in good health five months later This pyloroplasty with partial excision seems to be the right practice in bad organic stricture The dense tissue being cut away, the lozenge shaped incision can be readily sutured so as to become transverse whilst if a simple longitudinal incision is made through the tissues of a dense stricture it is impossible to convert it safely into a transverse line of sutured wound owing to the great tension if the two ends be made to meet in the middle If on opening the stomach or pylorus a

TABLE XVII —EXAMPLES FROM CASES OF PYLOROPLASTY OPERATED ON BY MR MAYO ROBSON

Date.	Sex	Age	Description	After history	With whom seen
May 24th 1897	M	39	In a letter dated May 13th 1897 the patient says "During the last 18 months I have suffered much pain The result of this trouble has caused me to be laid fast for two three or four weeks at a time and it has required another month or more for me to gain strength enough to move about 18 months before, the patient had epigastric pain several hours after food which was relieved by vomiting Since then his health had never been good and three and a half months ago he had a similar attack which was very severe and was accompanied with collapse The vomit contained blood 14 days ago he had another severe attack His normal weight was 10 st 10 lb. but it was now only 9 st. 3½ lb His stomach had been weak since childhood There was marked dilatation, but no tumour Operation There was a deep ulcer at the pylorus and extreme stricture barely admitting an ordinary director Pyloroplasty was performed a bone bobbin being used.	The patient completely recovered and gained his normal weight In a letter dated Feb 16th 1898 he says: I thought you would like to know that I am able to attend business as usual and have done so without interruption since July 19th 1897	Dr A. L. Matheson (Sheffield)
July 12th 1897	F	46	The patient was said to have had ulcer of the stomach 20 years ago Since then she had been subject to attacks of pain from half an hour to two hours after food sometimes it was continuous pain For three or four months there had been vomiting three times a day and the patient had lost a stone in weight in that time She had been leading the life of an invalid and was for a long period under medical treatment without benefit There were dilatation of the stomach visible peristalsis and tenderness over the stomach especially at the pylorus No tumour could be felt Operation: The stomach was much dilated and there was thickening at the pylorus Pyloroplasty was performed a bone bobbin being used	The patient made a good recovery She weighed 11st on Jan 8th 1898, a gain of over 2st In June 1898, there was some slight trouble with the stomach which subsided under treatment.	Dr T C Johnson (Aysgarth)
July 27th 1897	M	23	There had been vomiting and loss of flesh for two years The patient's weight was 10st it was now only 7st The dieting and lavage gave only temporary relief There were emaciation pallor and dilatation of the stomach but no tumour Operation There was much contracted pylorus and great hypertrophy the walls being more than one third of an inch thick Pyloroplasty was performed a bone bobbin being used.	The patient made a good recovery On Dec. 23rd 1897 his weight was 9st 13lb. and he was well	Dr Percival (Hillam) and Dr A. G Barrs
Dec 14th 1895	F	29	March 9th 1895.—She had had spasms for 10 years but pain more on the left side The attacks occurred two or three times a week They started without apparent reason and lasted an hour or two but sometimes persisted for 24 hours they were relieved by vomiting There were severe cramps in the legs. She had lost 2st in weight There was no jaundice but marked constipation There was rigid right rectus and no rigidity but tenderness to the left Dilatation of the stomach was well marked. Nov 22nd 1895 —Relief under treatment was followed by relapse There was now vomiting daily The patient's weight was 9st Operation The adhesions of the pylorus were separated. Active ulceration at the pylorus and tight stricture were found Pyloroplasty was performed a bone bobbin being used	On July 24th 1896, the patient weighed 9st. 5lb and was very much better There was a relapse in 1896 possibly from recurrence of the ulceration This was cured by gastro enterostomy In 1900 the patient was quite well	Dr C E Salter (Scarborough)

Koeppelin[11] reports a modification of the operation known as *submucous pyloroplasty* The horizontal wound along the pylorus is made through the two outer coats, serous and muscular, of the bowel and through the cicatrix, if there be one and the exposed and unopened mucosa at once bulges like a hernia The divided coats are then united vertically as in ordinary pyloroplasty Three reported cases of the submucous operation have proved successful The first patient was a girl aged 22 years who was subject to spasm of the pylorus The second patient was a woman aged 60 years, who had suffered from cancer Marked relief followed the operation 10 months later the second patient underwent gastro enterostomy with temporary benefit Jaboulay of Lyons performed the third submucous pyloroplasty last June The patient was a man aged 42 years, who had suffered eight years previously from symptoms of gastric ulcer, followed later by evidence of pyloric obstruction He at length vomited incessantly suffered from intense pain which necessitated large doses of morphine and became very thin polypus be found as a cause of the obstruction it must be emoved, and if necessary the operation can be completed by a pyloroplasty as in a case of my own mentioned under the head of tumours.

If the dilatation be dependent on an obstruction outside he stomach—as, for instance, a tumour of the pancreas, iver, or gall-bladder—relief may be given by removing the umour, or, if that be impracticable, by *gastro-enterostomy.* The instance reported by Dr. Ewart and Mr. Jaffrey[13] is a case in point where, vomiting incapable of relief by medical means was dependent on an aneurysm flattening out the pyloric end of the stomach and causing obstruction. The ollowing is an account of the operation with remarks by Mr. Jaffrey: "Dr. Ewart asked me to see this case in consultation with him on August 26th. There was a swelling midway between the umbilicus and the ensiform appendix which appeared to me to pulsate more freely than one would expect from a growth of the stomach lying over the aorta. However, taking into consideration the symptoms and the swelling we agreed that an exploratory laparotomy should be done. This I did on the following day. I made an incision from four to five inches long above the umbilicus. The stomach presented in the wound and on examination it was found to be quite healthy though dilated. On pulling the stomach out of the wound there appeared to be between from half a pint to one pint of fluid collected in the most dependent part of the fundus. The colon appeared to be normal and the walls of the stomach did not appear to be materially thinned. I attempted to press some of the fluid into the duodenum but did not succeed in getting much to pass, and on further examination the swelling which we had felt through the abdominal walls proved to be a large fusiform aneurysm of the abdominal aorta. It commenced about half an inch below the aortic opening of the diaphragm and extended to the level of the umbilicus. The pyloric end of the stomach was flattened over the convex surface of the aneurysm; so much so that it caused obstruction to the passage of the contents of the stomach into the duodenum. This seemed to me to be partly due to the weight of the dilated stomach and its contents and of the colon and omentum. I deemed it advisable to pull as much as possible of the stomach over to the right side of the aneurysm so as to relieve this pressure. As the stomach seemed inclined to remain in its new position I did not think it necessary to fix it any way. The patient rapidly recovered from the operation, the wound was dressed with dry cyanide gauze, and the sutures were removed on the eighth day. There was slight vomiting frequently recurring for several days in connexion with nausea excited by the smell of brandy. The alarming symptoms disappeared and the patient slowly improved and became able to take solid food and to walk for short distances. She complained of burning sensations in the epigastric region, and had general hyperæsthesia of the abdomen, but the pulsating mass was less easily felt; this was no doubt due to the fundus of the stomach being placed between the aneurysm and the abdominal wall."

If cancer of the pylorus be found to be causing the dilatation *pylorectomy* may be indicated if the disease be limited and there be no secondary infection, but if it be too extensive *gastro-enterostomy* will be the only treatment likely to afford relief.

CONGENITAL STENOSIS OF THE PYLORUS.

Maier (in Virchow's Archives) holds that a degree of congenital stenosis is a frequent, if not the most frequent, though unrecognised, cause of dilatation, and he cites a number of cases, mostly in adults, of chronic catarrh of the stomach with dilatation in which stenosis of the pylorus varying from three millimetres to one centimetre (the normal, one to three centimetres) was found. He is careful to distinguish between the congenital form and that due to catarrh, ulcer, and cancer, the acquired forms of stenosis, and gives his reasons for considering the stenosis primary and the catarrh secondary in the cases mentioned. He acknowledges, however, that clinically the distinction is extremely difficult. Basing his classification on the anatomical structure of the pylorus he distinguishes between a simple form of stenosis in which there is a round or slit-like narrowing of the pyloric orifice and a complicated form due to a hypertrophy of the longitudinal or of the circular fibres of the pyloric region. In the first case, where the longitudinal fibres are hypertrophied, the stenosis is usually conical in shape, with the apex of the cone at the pylorus and projecting into the duodenum after the manner of the os uteri into the vagina, but sometimes it is ring-like, the constriction then measuring as low as from four millimetres to five millimetres. When the circular fibres, on the other hand, are increased the form taken is usually that of a thick swelling, the lumen of the canal not being so much reduced as in the former case.

The interest of a case related very fully by Dr. W. K. Penn with an account of the necropsy by Dr. Maxwell Adams,[14] lies in its proving conclusively that congenital stenosis does occur in a form capable of relief by operation. The case was one of persistent vomiting from three days after birth until death, which occurred in the third month, and as the pylorus was hypertrophied and stenosed, but not adherent to neighbouring viscera, a pyloroplasty might have been curative. This form of stenosis may explain many of the cases of dilatation and catarrh of the stomach coming on in young adults without apparent cause, and it may also explain many of the cases of persistent vomiting set down to a vicious habit or to hysteria. To judge from the literature of the subject, this condition is not of frequent occurrence, but it may be more common than supposed, as necropsies are not frequently made in the case of children dying out of hospital, and persistent vomiting in infants is not a very uncommon event. Ewald also mentions it in its relation to dilatation of the stomach. The subject has been fully treated by Landerer[15] and by Maier.[16] W. Abel[17] records the first case of congenital hypertrophic stenosis of the pylorus treated successfully. The patient was a male infant, eight weeks old, the operation being gastro-enterostomy.

Two Lectures
ON
RABIES.

Delivered at the University of London on Feb. 13th and 20th, 1900,

BY JOHN ROSE BRADFORD, M.D., D.Sc., F.R.C.P. LOND., F.R.S.,
PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTION; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.

LECTURE II.[1]

Delivered on Feb. 20th.

GENTLEMEN,—I propose to deal in this second lecture with the question of diagnosis of rabies in man and animals.

The diagnosis of rabies may be considered from three points of view—the clinical, the post-mortem, and the experimental. It is, of course, most desirable to make the diagnosis clinically. This, however, is frequently difficult and sometimes impossible, and in the case of animals it is probable that the diagnosis is most often arrived at from a consideration of the post mortem lesions. These, however, are frequently not very characteristic and hence there may not only be difficulty in the diagnosis of the disease during life, but this difficulty may not be removed on post-mortem examination. The experimental method of diagnosis by inoculation affords a more certain means of arriving at an accurate conclusion than either the clinical or the post mortem diagnosis. It is, however, not infallible and in some cases, as I shall show later, it may be impossible to make an accurate diagnosis even by the experimental method. We will consider first of all the diagnosis of the disease clinically—that is to say, the diagnosis from the study of the symptoms. It will be necessary to consider the symptoms of rabies only in man, in the dog, and in the rabbit. As mentioned in my first lecture the occurrence of the malady among other animals is rare.

[1] Lecture I. was published in THE LANCET of March 3rd, 1900

Rabies exists in two forms—furious rabies and dumb or paralytic rabies—and in these two forms it affects man, the carnivora, and rabbits, but in man and the carnivora the furious form is by far the more common as an initial manifestation, and in rabbits the great majority of cases exist in the dumb form. Dumb or paralytic rabies does, however, occur in man and the dog under two circumstances—firstly, as a terminal phenomenon in the great majority of cases of furious rabies, and, secondly, as the sole manifestation of the disease. In the rabbit furious rabies is occasionally seen but it is rare, since during the last four years out of 414 cases of rabies in rabbits observed at the Brown Institution there were only some three cases of furious rabies, and it is a point of some interest that furious rabies can be transmitted by inoculation from one rabbit to another.

SYMPTOMS OF RABIES IN MAN.

I will deal first of all with the symptoms of rabies as presented in man. Three stages in its evolution in man may be recognised: (1) a prodromal period; (2) a period where the disease is fully established; and (3) the third or paralytic stage. In some cases the third stage may be absent, in others the prodromal symptoms may be absent, and, as I have mentioned before, in a few instances the disease exists in the human subject in the paralytic form. That is to say, the first and second stages may be absent.

1. *The prodromal period.*—We will consider first the prodromal symptoms, although these are often vague and, as is frequently the case in other diseases, are recognised as such only after the malady has declared itself. The most important of these symptoms are a general malaise and an alteration in the mental state of the individual leading him to become melancholy and tending to make him shun the society of his fellow-creatures. The patient also suffers from sleeplessness and when asleep his rest is disturbed by nightmares, and it is said that often the nightmare reproduces the scenes of the dog biting him. It is stated—and it is a point of some interest—that even in cases where persons have been bitten by dogs which were not known to be rabid, although they really were rabid, that during the prodromal period following the bite the patient suffers from a peculiar apprehension and vague dread. In the bulk of cases this apprehension or dread is readily explained owing to the fact that the sufferer generally knows or suspects that the dog or other animal was suffering from rabies, but it is definitely stated by various authorities on the malady that the same dread or apprehension may exist where this fact is quite unknown. Other prodromal symptoms are a certain amount of præcordial distress and also slight dyspnœa. The mental symptoms, such as melancholy and apprehension, may in some cases reach such a high degree of development as to amount to insanity, and it is a point of some interest that the virus of rabies may cause symptoms closely resembling those of insanity. The prodromal period is said to last from 10 to 15 days.

2. *The period when the disease is fully established.*—The second stage of the malady is generally ushered in suddenly with dyspnœa and, as I mentioned before, it may occur without any preceding prodromal symptoms. The dyspnœa is severe and very soon the characteristic spasm on attempt to swallow is seen. The patient on attempting to swallow is seized at first with a spasmodic convulsion which involves simply the muscles of the pharynx causing expulsion of the liquid or the substance through the mouth. Very soon, however, the spasm on the attempt to drink spreads to other muscular structures, and not only are the muscles of the pharynx involved but those also of the head and neck and ultimately those of the trunk and even of the limbs, so that an attempt to drink is followed by a more or less generalised convulsion. The convulsive seizures are, however, not limited to the swallowing movements, but the respiration becomes jerky, being interrupted by irregular contractions of the diaphragm producing a sudden and well-known gasp. It is this jerking respiration which has given rise to the popular idea that the sufferer barks. At this time the special senses become more acute, especially hearing and cutaneous sensations, and the period very soon arrives at which the convulsions of the disease are not only produced by attempts to swallow, but at the mere sight of objects or the hearing of sudden noises, or even a draught of air touching the bed-clothes or skin. During the whole of this period the apprehension that existed during the prodromal stage becomes further increased and the patient dreads—and his dread is seen in his face—all the things which will lead to the production of a spasm, such as a sight of fluid or the approach of bystanders to his bedside. It is not at all uncommon at this stage of the malady for a condition of furious excitement, or even one of actual mania, to develop. The frequency of the pulse is greatly increased. Fever is present and the temperature may even reach as high a point as 104° F. Glycosuria and albuminuria are often present. Death may occur from asphyxia during one of the convulsive seizures, but often the malady passes into the third or paralytic stage, which is characterised by a rapidly progressive weakness involving the bulbar muscles, then spreading to the larger muscles such as those of the limbs, and finally to the trunk muscles, and so causing death from cessation of respiration.

3. *The paralytic period.*—The duration of the disease is usually from three to four days from its onset and some two to three days after the first convulsion. In some cases, as I have already mentioned, the first and second stages of the malady are absent and the disease exists in the human being in the third or paralytic form. Under these circumstances, with or without prodromal symptoms, a rapidly increasing paralysis, involving first the extremities, then the trunk, and finally the respiratory muscles, occurs, and, as I mentioned in my first lecture, this paralytic form of the disease was recognised by Van Swieten,[2] and in 1763 Hoin described four cases of paralytic rabies occurring in man amongst eight individuals who were bitten by a rabid wolf.

SYMPTOMS OF RABIES IN THE DOG.

The early symptoms of furious rabies in the dog are, first and foremost, an alteration in the habits of the animal so that it tends to become restless, miserable, and sad, and it is noticeable that at this early period of the disease the animal is in no way savage. Soon afterwards it seeks solitude by hiding under chairs or in dark corners and very soon it suffers from attacks of excitement followed by drowsiness. It is rather characteristic of the malady that the animal wakes up suddenly without apparently realising its position and surroundings. Very soon the reflex activity of the nervous centres becomes increased, so that sounds and sights which before passed unnoticed now produce excitement and at this period of the malady the animal may bite strangers, although it is not usual for it to attack or bite those to whom it is accustomed. The appetite still remains good, but fever is present. In the third stage the restlessness becomes much more marked, the animal cannot keep still, and it attacks furiously surrounding objects and destroys them, biting the furniture and the carpets—in fact, anything with which it comes into contact. It is evident that at this time hallucinations are present, as it is not uncommon for a rabid animal to spring at imaginary objects in the air. The voice becomes affected, owing apparently to the commencing paresis of the larynx, so that the characteristic bark is heard, the main distinguishing feature of which is its peculiar long-drawn stridulous character dying away in a howl. During the earlier period of the malady the seat of the bite is hyperæsthetic, but now it becomes anæsthetic, and later the animal may not only in its excitement bite surrounding objects but it may even bite itself, and more especially, it is said, the region where it was itself bitten. At this stage, when the malady is fully established, there is considerable excitation of the genital organs and this is a symptom that is often marked in man. It is also characteristic of the malady at this period for the animal to wander away. The mad dog will often travel very long distances, and it is in this way that the disease is spread to other animals and to the human subject, as very frequently the strange dog is approached by other dogs who thus get bitten. The excitement becomes more and more marked and the animal more and more furious, and it is at this period of the disease that foreign bodies of all kinds are swallowed, such as wood, coal, hair, and straw. Soon the excitement diminishes and the animal becomes paralysed, the palsy very often commencing in the jaw muscles, and it rapidly spreads to those of the limbs, finally affecting the respiratory muscles and so causing death. The palsy may be hemiplegic or even monoplegic in its distribution, but, as just mentioned, it spreads rapidly. The duration of the disease in the dog is from two to ten days, but from four to five days is the more usual period. The most characteristic clinical features in the disease apart from the difficulty in swallowing—which is well established when the furious excitement is present—are the bark and the restlessness. In cases of doubt in the diagnosis of the disease the rapid onset of palsy after the excitement is perhaps the most characteristic feature.

---

[2] THE LANCET, March 3rd 1900, p. 592.

In the dumb form of the disease sensory troubles are not so marked and, as a rule, the prodromal symptoms are not very obvious, but careful observation will usually show that there has been some change in the habits and that the animal has become anxious. The palsy usually begins in the jaw, causing the well-known drooping of the lower jaw with the viscid saliva hanging from it, but the palsy may begin in other parts of the body and may be either monoplegic or hemiplegic in its distribution. The average duration of paralytic or dumb rabies is from two to three days and the symptoms in no way differ from the terminal symptoms in the last or paralytic stage of furious rabies. Glycosuria is found in a considerable number of cases of rabies in the dog and sometimes albuminuria.

SYMPTOMS OF RABIES IN THE RABBIT.

In the rabbit the most characteristic features of rabies are somnolence with gradually increasing weakness of the hind limbs which rapidly spreads to the body generally, while the general health remains good. Fever and polyuria are also present, and very soon twitching and convulsive attacks occur in which the spasms are generally of a clonic character, together with grinding of the teeth. The weakness of the hind legs is often so marked as to cause complete paralysis, and the rabbit will drag itself from place to place slowly by the action of its forelegs. Wasting, although present in the terminal stages of the disease, is not very marked before the onset of the palsy. It is very characteristic of paralytic rabies in the rabbit that the palsy, especially of the hinder extremities, becomes extremely well marked at a time when the general health of the animal has not undergone very great deterioration. It is common to see rabbits with complete paralysis of the hinder half of the body eating greedily. The presence of the clonic spasms and the twitchings of the trunk muscles at a time when the hinder extremities are paralysed is also very characteristic of the disease. There are many pathological conditions in which palsy of the hinder extremities occurs in the rabbit, so that this by itself is by no means characteristic of rabies. The characteristic feature is that the posterior palsy rapidly spreads to all the muscles of the body and occurs at a time when the general health is good, as shown by the nutrition of the animal and by its taking food. Furious rabies occurs occasionally in the rabbit and then the symptoms are not very different from those seen in the dog. It is a point of some interest that the furious form of the disease when it occurs in rabbits may apparently be transmitted from one series of rabbits to another by consecutive inoculations through a considerable number.

In man the diseases which have to be distinguished from the furious form of rabies are tetanus, mania, delirium tremens, and cases to which the term "lyssophobia" has been applied, where after having been bitten spurious symptoms of rabies become developed. The resemblance between tetanus and hydrophobia is really very distant, the spasms in the one disease being far more generalised and continuous and in the other more localised to the throat, at any rate in the early stages, and intermittent. The confusion, of course, is apt to arise between the two maladies owing to the fact that tetanus may follow a bite in the same way as it may be the sequel of any other wound. Apart from the difference in the distribution and character of the spasms one of the most important ways of distinguishing between the two diseases is by a consideration of the incubation period, that of tetanus being very much shorter than that of rabies. Cases of mania and delirium tremens sometimes present difficulty, especially where these maladies have supervened in patients after they have been bitten. One case has come under my observation where a woman bitten by a dog which was reputed to be mad suffered from symptoms of delirium tremens which were ultimately fatal and which were thought to be those of rabies. Experimental inoculation made from the medulla of the patient and from the medulla of the suspected dog showed the absence of rabies. It is not very uncommon for lyssophobia to be confounded with rabies, and in the *Annales de l'Institut Pasteur*[3] there is a very good description of a case of lyssophobia where the diagnosis was arrived at partly from a consideration of the incubation period, which was only seven days, and partly by the difference of the symptoms. In this case the patient had no difficulty in keeping water in his mouth and the spasm only developed when he attempted to swallow; and, in the second place, a draught of air only produced a spasm when it was directed against the mouth or nose, whereas in the genuine disease, as I have just mentioned, the slightest cutaneous irritation produced by the incidence of cold air is quite sufficient to cause a spasm. The case I have just alluded to as recorded in the *Annales de l'Institut Pasteur* recovered with simple treatment. The fact that symptoms mimicking those of genuine rabies may occur after the bites of animals in susceptible people is a point of considerable practical importance as regards the reported cures of hydrophobia by bath treatment.

In the case of paralytic rabies in man the diagnosis is much more difficult, as there are several affections of the spinal cord which may give rise to an acute ascending palsy and probably in the majority of cases a satisfactory diagnosis could not really be made without experimental inoculation.

The differential diagnosis of rabies in the dog is often difficult. First of all, in the furious form there are many diseases which may be confounded with rabies, more especially epilepsy and also the epileptiform seizures that are seen in dogs to accompany disease of the external and middle ear. In both these conditions an animal previously quiet and well-behaved will be seized with a fit which may be followed, just as epileptic fits in man are, by a very considerable degree of excitement. Such cases as this perhaps afford the greatest number of the cases of suspected rabies. There are several organic diseases of the brain, more especially the presence of cysticercus in the brain, which will cause epileptiform seizures which may be mistaken for rabies. It would not be thought that such a malady as rheumatism would be confounded with rabies in the dog, but the mistake has arisen owing to the painful and swollen joint having been roughly examined and the dog, irritated by the pain, has bitten a person—and very often the mere fact of a dog biting the individual is held to be sufficient presumptive evidence of the existence of rabies. Intestinal obstruction has also been confounded with rabies in the dog, both clinically and on post-mortem examination.

As regards dumb rabies the greatest difficulty in making the different diagnoses arises in cases of impaction of a foreign body in the throat. Both in dumb rabies and in this condition swallowing is impossible. Very often a history pointing to the swallowing of a foreign body can be obtained and it can be noticed that there is not, strictly speaking, true palsy of the jaw, and, further, the prodromal symptoms have not been present. At the same time, it is very unwise to examine carelessly the mouths of dogs suspected of suffering from impaction of a foreign body, as if the case be one of rabies it is possible that the disease might be communicated by rough or careless manipulation. Inflammation of the temporo-maxillary articulation in the dog producing immobility of the lower jaw has also not infrequently been confounded with rabies. In all the diseases in dogs which are liable to be confounded with rabies the isolation of the animal will speedily settle the question, inasmuch as the duration of both furious and dumb rabies is very definite and also the mode of spreading of the malady. This is especially true of dumb rabies.

DIAGNOSIS OF RABIES BY POST-MORTEM EXAMINATION.

There are two principal reasons why rabies cannot be excluded by a post mortem examination in animals. First of all because the animal is often killed in the early stages of the disease, before the lesions have had time to develop, and, secondly, because rabies may co-exist with other lesions, as, for instance, with the perforation of the stomach or intestines that may be produced by the ingestion of a foreign body. These are both very serious fallacies and they perfectly justify the statement that the disease can never be excluded by post-mortem examination. At the best the post-mortem signs are not very characteristic. In the dog the mouth and tongue are generally coated with dirty thick mucus and the mucous membrane is dry and red, and erosions, or even extensive ulcers, are not uncommon in the mucous membrane of the mouth. The salivary glands, and especially the sub-maxillary, are intensely congested and there is well-marked infiltration of the connective tissue of these glands As regards the stomach there are three points to notice. In the first place the organ contains no food; in the second place it may contain a very large number of foreign bodies of the most diverse description, such as wood, coal, bone, fæces, hair, and the like, and, thirdly, ecchymoses of varying size are commonly present The intestines are empty and retracted and signs of commencing nephritis are usually present. The urine contains albumin and sugar in some 50 per cent of the cases. The other lesions that are found, such as petechial hæmorrhages in the pleura and under the pericardium, are to be looked upon rather as lesions produced by the asphyxia, which is the common mode of death, than as intrinsic lesions dependent on rabies The greatest stress is usually laid by veterinarians on the results of the examination of the stomach in cases of suspected rabies, but the mere presence of foreign bodies and even of fæces in the stomach is most untrustworthy evidence of the disease. No conclusion should be drawn as to the probable presence of rabies unless together with the presence of foreign bodies in the stomach there is absence of food and unless ecchymoses are present

---

[3] Annales de l'Institut Pasteur, January, 1900.

In man post-mortem signs are also not very marked and very often a number of those actually found are dependent on the mode of death, as, for instance, the acute emphysema that has been described, which is probably dependent on the dyspnœa, and the death from asphyxia In the nervous system the blood-vessels are found to be injected, petechial hæmorrhages are not uncommon, and patches of softening have been described in the cord and medulla; the nerves are also hyperæmic, the salivary glands are congested, and petechial hæmorrhages are also found in the mucous membrane of the stomach Slight nephritis has been already described. In the rabbit the most important post-mortem signs are the congestion and ecchymoses of the mucous membrane of the stomach and intestine.

THE EXPERIMENTAL METHOD OF DIAGNOSIS OF RABIES.

A fragment of medulla or some other part of the central nervous system should be taken from the suspected case and placed in pure glyceride *After being in this from two to three days* the fragment of the medulla should be pounded in a sterilised mortar with some sterilised salt solution or bouillon, and an emulsion of it so made should be filtered through sterile muslin and a small quantity of it introduced into a syringe sterilised by boiling. The inoculations should be made either into the anterior chamber of the eye or subdurally, the latter is preferable owing to the fact I mentioned in my first lecture that by this means there is a greater certainty of communicating the disease Inoculation into the eye or intravenously, or even subcutaneously, may be successful, but there is not the same certainty as there is in the subdural method The aqueous humour was recommended more especially in cases where the material was suspected of being contaminated with other organisms with the idea that if the eyeball suppurated it could be removed, and at the same time the virus of rabies would have had the opportunity of infecting the nervous system through the optic nerve So that at one time it was not uncommon to inoculate into the aqueous humour if the suspected material arrived in a putrid state This procedure, however, is unnecessary, as in many cases brains have arrived at the Brown Institution in the hot weather more or less decomposed, and the inoculation of this decomposed cerebral material subdurally has not been followed by any septic complications So that in all my observations the subdural method of inoculation was used If rabies be present the symptoms usually declare themselves from 12 to 19 days after the inoculation, but it is important to remember that they may be delayed for as long as 40 days and that therefore even after inoculation one cannot exclude rabies until a period of something like six weeks has elapsed This, however, is unusual There is no difficulty in the diagnosis of experimental rabies if attention be paid to the point that the palsy in the rabbit is accompanied by clonic spasms, and the only difficulties that present themselves in the diagnosis of rabies experimentally lie in the fact that sometimes the brain injected is contaminated with other organisms, such as those of septicæmia, and so the inoculated animals die within two or three days of the inoculation, or else, as in the case quoted in my first lecture, advanced decomposition in the material injected prevents the manifestation of the activity of the virus of rabies

I will conclude my lectures with drawing attention to the incidence of rabies in this country during the last few years In the year 1892 there were 38 cases of suspected rabies reported to the Board of Agriculture. In 1893 there were 93, in 1894 248, in 1895 672, in 1896 438, in 1897 151, and in 1898 17, so that in the years 1894, 1895, and 1896 there was a very severe outbreak of rabies in this country In 1895 there were 45 suspected cases in London, in 1896 128, in 1897 19, and in 1898 one At the Brown Institution I investigated in 1896 168 cases of suspected rabies and proved the existence of the disease in 113 cases In 1897 there were 64 suspected cases and 25 real cases; in 1898 there were 17 suspected cases; and in 1899 there were 10 suspected cases, but none of them proved to be cases of rabies. It was, therefore, proved that out of a total of 259 cases of suspected rabies examined in the last four years rabies existed in 138, that is to say, in 53 per cent of the cases The experimental method is of the greatest value in providing accurate statistics of the incidence of the disease, but, as I mentioned in my last lecture, it is not so useful for the purpose of determining whether an individual bitten by an animal suspected of rabies should or should not undergo the Pasteur treatment owing to the fact that so long a period—at least from 12 to 19 days—must elapse before a conclusive answer can be given, and because in some cases the incubation period in the rabbit may be prolonged to a length equal to that of the usual incubation period in man—namely, six weeks.

THE TREATMENT OF RHEUMATISM,

WITH SPECIAL REFERENCE TO PROPHYLAXIS AND ITS CARDIAC COMPLICATIONS,[1]

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN

[IN his opening remarks Dr. Ewart compared rheumatism and phthisis in respect of their preventibility, discussed statistics of the prevalence and mortality of rheumatic fever, chiefly as observed in Scandinavia, and made a brief allusion to the subject of cardiac complications He then proceeded to consider]

THE INFECTIVE THEORY AND THE ARGUMENTS IN ITS SUPPORT

The meteorological argument —Newsholme[2] points out that rheumatic fever shares with several specific febrile diseases a greater prevalence in winter and spring and with some of them (enteric fever, scarlet fever, erysipelas, &c.) a marked association with a deficient rainfall, the effects of which in lowering the ground water would gradually develop in the subsoil conditions of temperature and dryness favouring the growth of any assumed telluric contagium, whilst a high ground water never accompanies an excessive prevalence

A strong argument is also derived from the observation that in England a relatively high temperature of the air is favourable to an increase of rheumatic fever, and that in London its great epidemics occur only when the mean temperature of the soil is exceptionally high—*i e*, over 50° F., particularly if it has been thus high for two or more years in succession

The bacteriology —The existence of a specific organism awaits further demonstration The doubts entertained as to the truly rheumatic character of so called acute rheumatism in the lower animals detract from the value of experimentations *in corpore vili* Organisms have been described in man by various observers to which Newsholme refers[3] Whilst ect evidence is still wanting, cogent arguments are based on inference by Newsholme in favour of a microbic *teries morbi*, saprophytic with a tendency to parasitism, iquitous in distribution but restricted in its spread by the mplexity of the conditions requisite for its growth, essenlly a soil organism and perhaps, like tetanus, capable of coming pathogenic only when directly inoculated; and the estion is asked whether rheumatism is a purely miasmatic ease, like ague, in spite of the prevalence of the two seases being apparently connected with opposite conditions soil and of rainfall, or a miasmatic contagious disease like teric fever.

[2] Milroy Lectures on the Natural History and Affinities of Rheumatic Fever, a *Study in Epidemiology* Cf THE LANCET, March 9th and 16th, 1895

[3] Cornil and Babes bacilli as well as micrococci, Wilson, cultivations, Mantle cultivations Petrone, the organisms described by Klebs in rheumatic endocarditis J P Popoff and Birch Hirschfeld, staphylococci or streptococci in joints and valves; Bouchard and Charrin, staphylococcus Triboulet, staphylococcus albus and aureus, Sahli staphylococcus aureus Sacaze staphylococcus albus, M L de Saint Germain, experimental arthritis by intravenous injection of staphylococci, Professor Leyden, and more recent observations are quoted by Pribram Der Acute Gelenkrheumatismus (Nothnagel, Specielle Pathologie und Therapie), Band v, Theil i, Wien, 1899

The epidemiological argument.—After suggesting that infecon might be conveyed (*a*) directly from person to person (*b*) indirectly from infective discharges gaining access to e soil from water, milk, or other foods, or from desiccaon in habitations, Newsholme[4] refers to the prevalence of e disease being occasionally concentrated in certain cities, in streets, or even in houses. Important instances of ese local epidemics are quoted. Ch. Fiessinger[5] reported at in a village of 500 houses 10 out of a total of 21 cases served in recent years had occurred in one street, four curring in the same house, and two in the same room. dlefsen,[6] at Kiel, found 728 cases occurring in 492 houses 00 houses for 108 cases)—viz., two cases occurred in one ouse 100 times, three cases in one house 27 times, four cases one house five times, five cases in one house five times, six ses in one house once, and seven cases in one house once. riedlander in the discussion on Edlefsen's paper stated that t of 357 cases eight cases occurred in one house twice, ven cases in one house once, five cases in one house once, ur cases in one house eight times, three cases in one ouse ten times, and two cases in one house eight times. antle[7] has recorded multiple cases in the same house, also instance of rheumatism running through a family. The idemic spread of rheumatism does not occur with explosive pidity as does that of measles or influenza, but with slow nd creeping progress, like that of diphtheria, taking years invade a country and years to die out of it.

The general conclusions reached from a study of the candinavian returns of cases and other returns are:—1. hat considerable irregularities occur in the yearly incidence f rheumatic fever sometimes such as to deserve the term epidemic" 2. That there are two kinds of epidemics, the ne "explosive," terminating in one year or at the most ree years, and the other "protracted," chiefly observed in rge centres of population, or in connexion with the tatistics of an entire country, being possibly made up of the usion of two or more explosive epidemics. 3 That the avourite years for epidemics in England were 1855–56, 1859, 864–65, 1868–71, 1874–76, 1884–85, 1888, and 1893 4. That o absolute periodicity can be traced though epidemics are pt to recur at intervals of three, four, or six years. But in nany instances a regular alternation may be traced between he explosive and the protracted epidemics—two of the ormer occurring between each two of the latter.

The clinical argument.—Much stress is also laid upon ertain clinical features which are analogous to those of ecognised specific fevers—viz.: (1) the mode of onset shivering, general aching, &c); (2) sore throat (80 per ent. of cases, J. K. Fowler); (3) the progress of the fever nd its various complications, particularly endocarditis (all iseases leading to the latter being, except perhaps chorea, nown to be infective); (4) the tendency to relapse relapses are common in erysipelas, pneumonia, influenza, c.); (5) the incidence of the disease mainly upon the oints, where the infection is buried (this might be an xplanation for the absence of any perceptible contagiousess); and (6) the specific power of the salicylic remedies which is compared with that of quinine in malaria and of he iodides in syphilis. Personal proclivity, which may be egarded as inherited, largely determines individual liability, s in all infections which are widespread or ubiquitous. As to the channel of infection Newsholme believes that it ies through the tonsils or some part of the nasopharynx. Since all knowledge of the incubation period s wanting we are able to think of a "latent parasiism" as conceivable, the latent rheumatic infection eing suddenly called into activity in individuals pparently healthy and not exposed to any infection. The well-known influence of injury, fatigue, and chill, all of which lessen the resistance of the individual, is analogous to the personal factor of inherited immunity or predisposition and cannot be regarded as negativing the infective theory. Finally, there is the weakness of the alternative theory—the lactic acid theory of Prout, Todd, and Richardson, its chief clinical evidence being derived from Sir Walter Foster's[8] observations. In his two diabetic patients the prolonged administration of lactic acid produced a rheumatic fever, but D. A. Harkin[9] has suggested that this might have been gout in disguise as the small joints were chiefly attacked. At any rate, if lactic acid were developed in excess this would occur through the agency of a micro organism, which would be, according to Newsholme, the essential cause of the disease.

The Prophylaxis of Rheumatism.

In this direction suggestions are still wanting. The benefits of notification are largely due to a stimulation of clinical observation and thought; and in the case of rheumatism the *clinical method* is specially recommended by the fact that none of the general determining factors of rheumatism possess the same prominence as the individual factor of predisposition.

General prophylaxis.—Pending fresh bacteriological revelations general prophylaxis seems to be limited to the scope of sanitation. Yet our modern improvements have not, as in the case of phthisis, resulted in a steady decrease; but the recrudescences which have occurred from time to time are consistent with Newsholme's view that desiccation of the subsoil may be at the root of the evil, since during recent years droughts have coincided with an increasing consumption of water by the water-supply companies. But it is not clear how this general indication is to be met On the other hand, we still trust to an obvious indication for desiccation of the surface soil, and particularly of the sites for houses, as well as of the habitations themselves. The prophylactic indications connected with climate and mineral baths can only find their application in connexion with the individual.

Individual prophylaxis.—In individual prophylaxis we seem to have hitherto neglected or missed our opportunities. Where does the weakness reside which lays a child open to insidious rheumatism or an adult to rheumatic fever, when others undergo the same depression, fatigue, or exposure with impunity? By what sign shall we tell the special predisposition? And if able to suspect its presence, how shall we best arm the subject against it? A study of the features characteristic of a rheumatic predisposition and of the earliest rheumatic premonitions or of the prerheumatic state is an obvious requisite. For instance, as regards the general physical appearances, although physicians may have derived general impressions from a prevailing tendency to pallor, sallowness, imperfectly cleared skin, and the like, they have not been able, so far as I know, to frame a typical "facies" peculiar to the predisposition; but to this point I dare not devote further time.

Rheumatic tonsillitis.—The great frequency of rheumatic tonsillitis has its significance. The tonsils, which are strongly suspected of introducing and of harbouring the germs of phthisis, have also been suggested as portals of infection by the supporters of the infective theory of rheumatism. But there are other sufficient reasons for not neglecting them as possible factors in the disease. May not indications be traced in their behaviour or aspect which might aid us in recognising the rheumatic proclivity? Again, is the frequent immunity from arthritis, in spite of a liability to carditis, in any way connected with the more active function of the tonsil in early life? Can anything be achieved by treating the tonsils which could in any way influence the rheumatic bias? This practical question might conceivably be answered by the results of surgical interference. Has the rheumatic tendency been favoured or in any way affected by a removal of the tonsils and of adenoids? If any connexion were traceable between the rheumatic tendency and the behaviour of the tonsils valuable indications might be gained by a systematic examination of children at schools and in private practice with a view to prophylaxis.

Prophylaxis by climate, environment, and general management.—This includes the most important indications, which are also those least within reach for the majority, particularly as regards selection of circumstances; and much is also implied which it may become easier than it now is to formulate. Prophylaxis against a disease so largely affecting young life cannot in cases of suspected indisposition be undertaken too early, perhaps even in infancy, with the twofold object (1) of avoiding individual exposure, and (2) of increasing individual resistance to its causes. Early childhood and early school days are the special periods during which watchfulness is needed, for there is reason to believe that among the poor the predisposed children fall early victims to their adverse circumstances when, in addition to the evils of damp, of cold feet, and of underfeeding, there is a wasteful leakage of energy wanted for visceral innervation into the service of mental effort and school worry. We learn the importance of schools being removed from town into country. For predisposed children the selection of schools should be largely guided by considerations of school hygiene and of local climate, atmosphere, and soil, concerning which we yet know too little. Is rheumatic fever ever developed at sea? Is the rheumatic tendency counteracted by marine climates, and if so, by which variety, the soft or the bracing? Too much stress cannot be laid upon the importance of management and regulation of the alimentary functions in this form of delicacy. Errors in quantity and in quality of the food, imperfect digestion, unrelieved bowels, checks, both acute and chronic, to the action of the liver, lymphatic embarrassments, which are passed over as trivial in average children, are dangers to the predisposed, and the physical appearances, particularly those of the complexion, abdomen, tongue, and pharynx, may be health-saving guides.

Prophylaxis by drugs.—Is salicylate indicated? Various remedies will serve the purposes of internal hygiene, but information is needed as to the tonics best suited to counteract the early rheumatic bias With special reference to the iodides and to cod-liver oil are the indications analogous to those approved in the scrofulous predisposition? But our most immediate concern is the prophylactic use of anti-rheumatic remedies at all stages of the liability. Belief in the specific virtues of the salicylates would almost imply as a duty its systematic administration in all threatened individuals. Unhappily, that belief is shaken by instances in which fresh arthritic attacks have occurred whilst the patients were taking salicylates. But putting aside that doubt some good probably results from periodical courses of salicylate treatment for the sake of its hepatic action. The responsible question remains, "Can its continuous administration be detrimental, particularly to the young?"

THE VARIETIES OF ACUTE RHEUMATISM, WITH SPECIAL REFERENCE TO THEIR LIABILITY TO CARDIAC COMPLICATIONS.

In spite of its rapidly advancing cleavage the rheumatic group is still unwieldy. Its recent contraction owing to the identification of various specific microbes or toxins may be argued in support of, though truly it may also be argued in opposition to, the assumption of an infective nature of the remainder. Pyæmic, gonorrhœal, post-zymotic, and other secondary arthropathies are no longer spoken of as rheumatism; and as to those infective forms which have been less completely differentiated, the name "pseudo-rheumatism" sufficiently declares their dissociation from the group. Whether a single or several specific infections may yet be detected in the latter will be determined by further bacteriological studies; at this stage a purely clinical analysis of its members would seem to be possible d expedient. But any sorting of our cases is merely prosional. In phthisis different types of disease have been nstructed when the difference was simply between the nstitutions or structural peculiarities of the subjects, and e same might happen with rheumatism.

The distribution of the arthritic lesions.—Arthritic lesions, regards their local incidence and their varying tendency localisation and the order of their migrations, are tangible atures which may serve as indicators to the more essential at less obvious contrasts and affinities between acute eumatic and rheumatoid arthritis. Four broad types and out clearly. 1. Monarthritis. Whether rheumatic or eumatoid, this is in both affections an outlying and ysterious variety, equally untrue to the accepted definition and to the usual type of either, and therefore straining all our theories. 2. Symmetrical rheumatoid arthritis. A systematic bilateral and symmetrical progress is typical of rheumatoid arthritis, both acute and chronic, and in strong contrast with the third type. 3. Non-symmetrical or erratic rheumatic polyarthritis. In its most acute form, which we may suppose represents the true type of rheumatism, the polyarthritis is conspicuously non-symmetrical. It is erratic as well as migratory, attacking first, it is said, those joints which were most in use, but subject to no obvious rule in its wanderings. Symmetry, when it does occur—and this is perhaps not more frequent than belongs to the law of chances—would seem to be an exception rather than the rule and a departure from the purest type. 4. "Symmetrical rheumatism," acute and subacute. In some cases, usually not the most severe and often subacute, symmetry is a prominent feature of the arthritis. The more I have looked for this symmetrical condition the more frequently have I found it and the more have I been impressed with certain peculiarities in the cases which presented it. The following tabulation of the rheumatic series is an attempt to follow out the gradual transitions which may establish a distant connexion between its two extreme representatives. Chronic fibrous rheumatism, which is not included, would unnecessarily complicate the table.

CLINICAL CLASSIFICATION SHOWING TRANSITIONAL VARIETIES.

I. Chronic rheumatoid arthritis.	Su -variety (*a*): with symmetrical, permanent incurable deformity.
	" (*b*): with symmetrical deformity capable of some degree of recovery.
II. Acute and subacute *rheumatoid* arthritis.	" (*c*). distinctly "rheumatoid"; heart not affected.
	" (*d*): "rheumatoid" in the local persistence of its joint lesions and "*rheumatic*" in its heart lesions.
III. Acute symmetrical rheumatic arthritis.	" (*e*) with persistent and refractory joint mischief (a rheumatoid feature) with or without heart lesion.
	" (*f*): with transient joint mischief and no permanent heart lesion
	" (*g*): with permanent heart lesion and transient joint lesion.
IV. Acute cardiac rheumatism without arthritis ("juvenile" type).	" (*h*)· joint pains only (usually bilateral) with cardiac lesion.
	" (*i*): febris rheumatica sine arthritide
V. Acute rheumatic polyarthritis.	" (*j*): polyarthritis without heart lesion
	" (*k*): polyarthritis with heart lesion.
	" (*l*): hyperpyrexia and various acute complications.

In the fifth group "polyarthritis," a sub-variety (*j*), is made up of cases without heart lesions. The percentage of the latter may eventually be found to be less common in the acutest rheumatic attacks and weighty questions of treatment might be opened up thereby; in this connexion it may be helpful to remember that the most active production of valvulitis occurs in Group IV. from subacute and almost latent attacks in the young.

Acute symmetrical rheumatism.—Among those other purely tentative distinctions suggested as possible helps to study special attention is called to Group III. and to its sub-varieties. The acuteness of the arthritis in this symmetrical rheumatism has seemed to me to be usually not of the first order, but its tendency either to stay or to return is exceedingly marked. This peculiarity may be developed to any degree from that represented in the sub-varieties (*f*) and (*g*) where the symmetrical affection of the joints closely resembles, but for its systematic distribution, the ordinary acute polyarthritis, down to the condition found in sub-variety (*d*), where the persistent or steadily relapsing character of the arthritis and the eventual deformity identify the case as "rheumatoid," in spite of its originally purely "rheumatic" appearances and of the heart lesion which is so frequently found to co-exist. Indeed, the most important of the features of the whole group is the frequent implication of the heart. It would be important to determine whether the cardiac lesions are, as I think, always of the verrucose type rather than of the vegetative, and whether pericarditis is or is not relatively more frequently associated with it than with the non-symmetrical variety.

The practical difficulty of separating the rheumatoid sub-variety (*d*) from the rheumatic sub-variety (*c*) is great, so closely do some of the cases in the latter imitate the rheumatoid characters In some of these acute or subacute rheumatic attacks the affection is confined to, or settles plan and should be preferred. A strong case has been made out in favour of the alkaline salicylate method; for the other method no positive argument has been advanced so far as I know. There would seem to be a natural fitness in associating in our treatment two remedies the virtues of which seem to complete each other, the sphere of the salicylates being the rapid control of the pyrexia and of the arthritis, that of the alkalies the control of the tendency to endocarditis. But it is essential that we should learn from overwhelming evidence the full extent of the advantage which our patients might gain. Meanwhile, a hope has been raised by Dr. R. Caton's[18] favourable report on his treatment by a series of small blisters together with the administration of sodium or potassium iodide that the best results of the combined alkaline and salicylate treatment may yet be surpassed.

THE THERAPEUTIC ACTION OF SALICYLATES IN ITS BEARING UPON THE PATHOLOGY OF RHEUMATISM AND OF THE RHEUMATIC HEART AFFECTIONS.

It is noteworthy that salicylates do not depress a normal temperature—a circumstance pointing rather to a sedative action than to one upon the metabolism of the body. Dr. Archibald Garrod distinguishes between the hyperæmic and the fibrous rheumatic changes and ascribes to salicylate treatment considerable power over the former. Possibly the refractory cases are those which present pre-eminently the latter tendency. The tendency of some of the "symmetrical" as well as of all monarthritic attacks to become localised agrees with that view. The same distinction between the hyperæmic, fluxional, or vaso-motor and the fibrous morbid changes has an important bearing upon the pathology of the cardiac lesions. But when we turn to the valves which are the chief seat of the cardiac lesions the nervine theory has no place. Our pathology becomes, like the tissues of the part, independent of vessels and of vaso-motor nerves. Cells and juices are the only material for our speculations. The juices, known to be unhealthy with that tendency to hyperfibrinosis which is common to all pyrexia but is specially conspicuous in the acute rheumatic state, probably irritate and swell the intercellular channels and the cells which they permeate. The endothelial cells probably suffer most from the rheumatic malnutrition, perhaps even to the point of necrosis and disappearance. Local deposition of fibrin is the disastrous mode of repair which finally leads to fibrosis and crippling of the valve. Whilst the vascular membrane suffers in this way similar influences probably overtake the endothelia of the lymph-channels. These changes need further study; they may include swelling of endothelial cells, inspissations of lymph, and partial obstructions. We can judge only of their results in the shape of infiltration and swelling of the fibrous tissues. These two agencies respectively at work at the surface of the valves and in their thickness combine to bring about the well-known changes of valvulitis. From this simplified conception of the valvular lesion we may work back to the arthritic morbid processes and distinguish in them a mainly extravascular set of changes which in some varieties of arthritis are inveterate and refractory to our present methods of treatment, and the vaso-motor changes represented by the passing hyperæmic and fluxional swellings which so rapidly disappear in favourable cases under the influence of salicylates.

If these views be correct we may regard rheumatism as largely made up of a perverted metabolism and of its damaging effects upon the lymphatic structures, including in some cases the serous membranes, and, on the other hand, upon the vascular endothelium. The failure of salicylates to check the cardiac complication need not imply that the rheumatic process in the heart is different from that in the joints. The mechanical conditions alone differ. The joints can rest, but the heart and its valves never do. There is, however, another paramount determining factor, that of predisposition.

Endothelial vulnerability.—The frequency of zymotic or post-zymotic valvulitis and arthritis may bear the interpretation that in early life endothelial structures are singularly susceptible, particularly in those extravascular tissues which are exposed to much work, such as the membranes of the valves and the joint structures. Yet, since not in all children, but in a minority only, is the heart affected after measles or scarlet fever, and since most children also escape cardiac rheumatism, the endothelia of those who suffer may be regarded as specially vulnerable. This brings to mind the analogous liability, traceable through families, to the changes of atheroma. We are also reminded of individual differences noticeable in the skin, particularly in relation to eczema. Some skins develop eczema under the slightest provocation, others even under strong irritation are almost incapable of it. An analogous vulnerability of the endothelia, such as is seen also in phthisis, might explain some of the rheumatic events. The peri-articular rheumatic swellings and the inflammatory exudations occurring in situations where no blood-vessels are found and at the surface of serous membranes might possibly be viewed as the result of damage to a specially vulnerable lymphatic endothelium. To this might be partly due the œdema of the extra-vascular tissues of the valves, the surface lesions of which are lesions of the vascular endothelium. If this excessive vulnerability could be identified in its bearers at an early age the road might be paved to an efficient prophylaxis.

THE RHEUMATIC HEART COMPLICATIONS AND THEIR PROPHYLAXIS.

Whilst the recognition of fully-developed rheumatic fever presents no difficulty the same cannot be said of the minor and insidious forms of acute rheumatism. Leaving aside the list of pseudo-rheumatisms which includes various articular affections referable to toxic and to infectious agencies, variability in the localisation and in the degree of the lesions is a prominent feature of the rheumatic group. Any implication of the joints is readily ascertained, but the condition of the heart cannot in a large proportion of cases be determined with certainty. Though no murmur be audible it is impossible to prove the complete absence of some minor affection, the signs of which may develop only at a late stage. The researches of Dr. D. B. Lees and Dr. F. J. Poynton have raised our estimate of the frequency of rheumatic carditis and its results as distinct from simple valvular affection. Indeed, it is a safe rule to frame our treatment on the assumption that the heart is threatened in all rheumatic attacks. Its continued activity, not always restrained by a merciful immobilisation of acutely inflamed joints, is an abiding risk. Nevertheless, we have reason to believe that it is not in every case inflamed or strained beyond its normal holding. Judging from rough clinical standards and from the progress of cases the occurrence of pericarditis is the exception and that of myocarditis and dilatation is far from being the rule. Not only is valvulitis the prevailing danger, but, as pointed out by Dr. A. E. Sansom, valvular disease may often arise secondarily as a late result of changes which were originally myocardial.

Much importance attaches to the fact that from the severe arthritic attacks to the cases of febris rheumatica sine arthritide, again recently brought to notice by Dr. C. O. Hawthorne, cardiac lesions may accompany every form of arthritis, but their frequency and their degree are not proportionate to the degree of the joint affection or to the intensity of the rheumatic attack. As hinted above, acute immobilising arthritis is in some measure protective to the heart. Is it protective otherwise than in the measure of the mechanical rest afforded? Is the heart less safe when the articular effusion as well as the pain has been dispelled? This is a question with important therapeutical bearings.

The treatment by vesication.—The claims of the treatment by blistering, which was introduced long ago by Herbert Davies and recommended by Harkin, will be dwelt upon with special authority by Dr. R. Caton and a few brief remarks will serve the present purpose. The evidence which has been produced is too important to be lightly put aside. Knowing that blistering is harmless we may avail ourselves of any help it may give. Multiple blisters over the joints (Davies) or a large blister over the heart (Harkin) would have equal opportunities of influencing and curing the rheumatism if, as it was alleged by them, blistering is a cure. If this or any other treatment were found to safeguard the heart we should not hesitate to give up the exclusive use of salicylates; but for the mere relief of the arthritis blistering the joints, although efficacious, is now in most cases just as superfluous as the ice-bags which were applied to them long ago by Esmarch. Since the cardiac inflammations have not been prevented or suppressed by our internal medication they should not be denied any advantage such as that which præcordial blistering professes to confer. There are sufficient indications for a renewed inquiry in this direction both from a general therapeutical and from a sero-therapeutical aspect I have been struck by the circumstances that immunity from heart lesions often coincides with very free arthritic effusion and general acuteness of symptoms. Is this a guide for our treatment of those cases where, as in childhood, little or no articular effusion occurs? If so, prophylaxis might demand in predisposed subjects the application of blisters for the threatenings of an attack. The size and the frequency of application are practical points for discussion; and for the supporters of the infective theory of rheumatism there is the additional question whether there might be any advantage in the re absorption, from constantly recurring vesications, of systematic doses of a serum presumably endowed with anti-toxic properties, or whether the blisters should be treated by incision and allowed to act merely as revulsive, derivative, and counter irritant remedies.

---

[18] R. Caton, THE LANCET, August 17th, 1895, p 399 Cf. Edinburgh Medical Journal, 1899; also Transactions of the Clinical Society of London, March 9th, 1900.

THE GENERAL TREATMENT OF THE ACUTE ATTACK.

It were almost presumption to touch upon this subject in this assembly were we not all conscious that in spite of the predominant position taken by the salicylate treatment considerable divergence still obtains in our practice and a brief statement of views may be expected of me The keynote of the condition is general embarrassment of metabolism specially evidenced by the characteristic persistence of anorexia and failure of excretion. Chief and paramount is, therefore, the indication for free outlets, whilst supplies must be carefully measured. Purgation would seem to be the first and essential duty and it will be best carried out by remedies promoting the flow of bile It has been a question in my mind whether rheumatic arthritis could long co-exist with diarrhœa Extreme purgation could never be a suggestion of treatment, but no trivial consideration should interfere with a systematic and full relief of the bowel.

Remedies which promote the tendency to perspiration—and this is one of the recommendations of salicylates—are indicated in preference to those likely to check it. The need for diuresis is sufficiently manifest in the loaded condition of the urine and is usually met by the diuretic properties of our remedies and by an abundant supply of fluids These general measures efficiently carried out are a considerable portion of the cure, but the employment of special remedies should not be delayed. Probably the sodium salt of salicylic acid is the best to administer—though the strontium salt is favourably reported upon from America—and should be given in full doses. In the presence of albuminuria all salicylates should be strictly barred and we should rely upon a mild alkaline treatment Alkalines have appeared to me to be the most essential part in the treatment in all cases, and whether sodium salicylate be also administered or not I venture to think that they should never be omitted. The potassium salts are usually preferable to those of sodium, and for reasons which I have explained the potassium citrate may be largely or entirely substituted for the bicarbonate. Both the alkaline and the salicylate treatment should be continued with diminishing frequency of administration for two weeks after the cessation of joint symptoms, and the urine kept alkaline during convalescence partly through the agency of diet. As the salicylate is diminished quinine, which may be needed from the first, is added or increased. Absolute rest in bed for a fortnight or longer and a gradual return to activity are rigid rules. Blisters may be applied from the first as a prophylactic measure, and as a curative measure in all cardiac affections, and especially in pericarditis.

It is time that I should briefly refer to the iodides of sodium and potassium long in favour for the treatment of chronic rheumatism, also of undoubted service in the acute stage of rheumatoid arthritis and likely to be useful in some of the cases included in Group III. in the sub-variety, (*e*) of the symmetrical form of rheumatic arthritis when the skin is sufficiently tolerant But it is in the treatment of acute rheumatism that Dr. R Caton has brought forward strong evidence in favour of a specific action of the iodides, when combined with continued vesication over the chest, in preventing and in curing endocarditis They would seem to be specially recommended by the influence which they exercise upon the lymphatic system on the one hand and upon the blood on the other. I need not dwell upon the evidence of their power to facilitate the lymphatic flow which should be of service in removing the products of arthritis. A more important action may be exercised upon the blood.

Iodide of potassium has been largely prescribed with a view to the consolidation of aneurysms. I have prescribed it in considerable doses for considerable periods, but after continuous treatment extending over months the post-mortem examination has revealed no clotting within the sac. This *has led me to the conclusion that the tendency of* the iodide is to lower the coagulability in spite of the favouring influence of a diseased arterial surface and to expect good results in a disease where the absence of clotting is the great end to be secured.

The potassium salt would seem to be best suited to the acute form of the disease, but in the rheumatoid cases and in the rheumatic cases approaching to the type of rheumatoid arthritis the sodium salt probably would prove less depressant and, so far as my observations go, is sufficiently satisfactory in the result.

During convalescence iron is not tolerated unless associated with adequate purgation and alcohol is not needed in average cases.

Attention must be paid to the varied requirements of individual cases. The heart being concerned gastric inflation should be guarded against and relieved. A totally different treatment, so far as I have observed, is called for in the monarthritic acute rheumatic attacks.

THE LOCAL TREATMENT FOR ARTHRITIS AND THE CONSTITUTIONAL TREATMENT FOR RHEUMATISM: THEIR SEPARATE SPHERES AND THEIR COMBINATIONS.

Most of the acute rheumatisms are now treated exclusively by drugs. Sometimes drugs entirely fail and recovery is delayed until it is realised that the arthritis and not the rheumatism is the thing to treat. But other cases need a judicious combination. The proportion in which local treatment is needed may be roughly measured in individual cases upon that of the tendency to localisation, as I shall now endeavour to explain.

The treatment of acute monarthritis.—Here little of the internal treatment which has been described is appropriate except that relating to the *primæ viæ*. The primary indication is to treat the joint (by splint and bandage, elevation, leeches or preferably blisters, inunctions, and graduated pressure); and the next to support the patient in the direction where support is most needed Most often quinine or bark with nerve tonics and stomachics are indicated in addition to mild salines. A depressing treatment by salicylates and strong alkalies is worse than useless and its prolonged and unsuccessful trial often impairs the powers of recovery.

The treatment of the "acute rheumatoid" and of the "symmetrical rheumatic" attacks —As regards the necessity for local treatment the nearest approach to the monarthritic type is to be found in Group II., but the kind of local treatment needed may be totally different. As I have insisted elsewhere,[19] in harmony with Fuller's teaching many, though not all, of these inveterate or relapsing pyrexial cases, alike refractory to salicylate and to alkalies, are made worse by continued rest and are curable by movement and by a supporting treatment But the acute arthritic swelling needs first to be subdued by Esmarch's ice application or by ice massage. None of the anti rheumatic medicines or of the dietary restrictions are needed in these cases, the treatment of which cannot be given here in its full detail. This part of the subject would not be complete without a mention of the surgical treatment which has been advocated and practised by Dr. J. O'Conor of Buenos Ayres, but of which I have not had personal experience. Some cases in the same group have stronger rheumatic features and in that proportion may get relief from salicylates, though local treatment should not be neglected. But it is in Group III. that we find the chief variety of cases needing adjustment between the local and the constitutional treatment. Without attempting to enter into detail, instead of dealing with an unyielding attack by increasing and oppressive doses of salicylates we should trust to milder measures, those of internal hygiene and of diet, and to a saline treatment sufficiently alkalising to protect the heart, associated with quinine, nerve tonics, or stomachics, as each case will seem to suggest. The question of blistering the joints or the præcordium is one which should be earnestly considered in this set of cases The local measures may have to be tentative, like our medication, and may include leeching, ice massage, bandages, or even splints.

DIET.

Diet is the last part of my subject but by no means, in my estimation, the least important The conclusions which may venture to put forward are that rheumatism is in art a dietetic disease and that in the wide range of our ases the "feeding" plan needs to be represented as well as he "starving" plan. In rheumatic fever the diet cannot e too light. Nature refuses food and the state of the ongue forbids it; but plenty of water is needed to clear the way for food.

---

[19] Cf Medical Press and Circular, 1899

The source of the over-supply of lactic acid has been traced in our theories to the decomposition products of muscle and therefore meat and beef-teas have been gene- ally held detrimental, but the inability of some patients to manage milk diet has led me to question whether milk might not in them keep up the rheumatic tendency and become the ecurring supply of acid. There is evidence that fermentation s set up in the stomach as well as on the tongue and this s another source of dilatation of the stomach to which I would call special attention. I have arrived at the conclusion that administering a small quantity of salt (15 grains to the half-pint) or adding it to the milk is an important indication in all cases of exclusive milk diet and usually renders its previously difficult digestion easy. This is also an indication in dyspeptic infants who are sometimes supposed to be intolerant of milk.

I am glad to find in Dr. Burney Yeo's "Manual of Medical Treatment" that he has recommended a salted alkaline milk drink in acute rheumatism. Clinical observation has, however, suggested to me another line of diet, the further trial of which I may safely invite. A temporary vegetarian diet seems to be as much indicated by the rheumatic state as the avoidance of animal food, and in refractory cases it is possible that the administration of soups made of a variety of vegetables such as I am now prescribing at St. George's Hospital supply the food as well as in part the medicine required. Whilst meat renders urine acid, vegetables render it alkaline, and this is the result at which we aim.

I have reached the end of this cursory sketch of an almost unlimited subject. The points for elucidation are many but they may be grouped under few heads and these have been sufficiently indicated. The main questions which I submit for your discussion are: How shall we prevent rheumatism? and, How shall we put a stop to the rheumatic heart evil?

SOME REMARKS ON EXTERNAL URETHROTOMY.

By REGINALD HARRISON, F.R.C.S.ENG.,

SURGEON TO ST. PETER'S HOSPITAL.

THE *examination in the out-patient room of a patient who* was operated upon for stricture by external urethrotomy over a year ago gives me an opportunity of referring to some points connected with this operation to which I attach importance. The case may be taken as a typical one of its kind, of the details of the operation employed, and of the results to be aimed at.

This patient was a man, aged 47 years, who had suffered from stricture of the deep urethra for several years. He had been treated by various methods of dilatation but with no permanent benefit and attacks of retention, hæmorrhage, and cystitis had been frequent complications. At the end of 1898 I took him into hospital and performed an external urethrotomy in the following manner. As the stricture would only receive a filiform guide an internal urethrotomy was first performed with Maisonneuve's instrument. Then a full-sized grooved staff was passed into the bladder to complete a perineal section. Exploration with the finger from the perineal wound enabled me to detect some stricture fibres which had escaped the internal urethrotomy and these were divided with a probe-pointed bistoury. Then I could pass my finger readily into the bladder and forwards along the urethra towards the external meatus, thus showing that the constriction had been completely removed. A full-sized gum elastic bladder drainage-tube was passed into the bladder and secured. For the latter a flexible rubber one was substituted on the fifth day and after 16 days' drainage and irrigation so as to keep the divided stricture thoroughly cleansed the wound was allowed to close and the patient left the hospital after a stay of three weeks. During the after-treatment the distal portion of the urethra was washed out and kept clean by syringing from the external meatus and so out by the wound. He was instructed to use a full-sized bougie and to report himself from time to time, but as he remained well he did neither. Fancying, however, after a recent attack of influenza, that there was something wrong with his urine he came to see me. There was nothing amiss with the urine beyond an excess of urates, and I was able to pass a series of bougies of No. 10 (English) to No 15 (French 26) easily and without pain. I usually select Maisonneuve's instrument in these cases for the preliminary internal urethrotomy, as it will enter any stricture, however narrow, without any preceeding dilatation, by means of its filiform guide. Some prefer a urethrotome which divides the stricture from behind forwards, but I do not think this makes the least matter *so long as* the end of the instrument is fairly within the bladder. The kind of drainage tube referred to is made in different lengths and sizes in gum-elastic to fit the wound and deep urethra and bladder with as much accuracy as a tracheotomy tube fits a windpipe. From the day when it is inserted it commences to mould the repairing urethra to the dimensions required. It is readily used or temporarily removed for the purposes of irrigation and cleanliness, and when any slight risk of bleeding or oozing which might require side-packing is over its place is taken by a soft rubber tube with depressed openings of similar dimensions. Thus cicatrisation proceeds up to the time of its final removal. I first had these tubes made for me in the days when lateral and median lithotomy were common operations. On several occasions when there was oozing or free bleeding which could not be readily stopped I inserted one of the largest of these tubes, of about the dimensions of an average thumb, and closed in the incision around it firmly with sutures. This invariably arrested the bleeding, whilst the flow of urine remained uninterrupted and the patient was readily kept quite dry. This is the most effectual and convenient way of arresting bleeding in this class of operations.

I might have added further illustrations in correspondence with the case I have related where patients have been under observation for long periods, but after what I have already written elsewhere[1] this is hardly necessary.

External urethrotomy seems specially applicable to the following classes of cases.

1. To resilient and rapidly contractile strictures in the deep urethra, which, like burn-scars, are unamenable to stretching or dilatation and where a splice or an interval of new tissue is required within the circumference of the contraction. It was in this class of cases where dilatation had failed or recurrence had occurred that Syme first demonstrated the permanent advantages of this operation.

2. In cases where the wound made by an internal urethrotome is out of proportion to the natural drainage possibilities of the urethra A wound may be so constructed within this canal as to never drain completely either in regard to urine or to its own discharges. The result is much the same in these circumstances as what follows accidental lacerations of the urethra. Some years ago I demonstrated in a considerable number of cases that partial ruptures of the urethra from violence, when treated promptly by perineal section and drainage, were no more liable to be followed by traumatic strictures than either a median or lateral cystotomy for stone. I was led to draw this conclusion and to apply it in practice by noticing that it was the slighter cases of ruptured urethra either not treated at all or by the retention of a catheter which were followed by the most dense and contractile forms of traumatic stricture, whereas the severer cases, where the rupture was so extensive or so complete as to render the introduction of the latter instrument impossible and to necessitate a perineal section with bladder drainage, did the best and were much less liable to the subsequent formation of a stricture at the site of the wound. Surgical cleanliness and drainage were evidently important items in the prevention of the latter. In dealing with any lesion of the urethra, made either accidentally or surgically, we must feel fairly sure that the unaided efforts of the wounded canal are sufficient to furnish adequate drainage, otherwise this should be artificially supplied. It is reasonable to infer from these observations that in the larger proportion of cases where internal urethrotomy gives excellent results the operation precisely fulfils the required conditions—namely, the complete division of the stricture by a wound which the urethra itself is capable of draining. It is no doubt possible in

---

[1] Surgical Disorders of the Urinary Organs, fourth edition, 1893

some instances where considerable wounds are made within the urethra to supply the necessary drainage by the retention of a catheter for some days after the operation This expedient, however, often breaks down, as in the case of accidental injuries, and is not so reliable or cleanly as the external incision and drain tube These provide alike for the urine as well as for the discharges of a wound, which can only be imperfectly placed under antiseptic influences

3 In cases of stricture complicated with urinary fistula and sinuses The division of the stricture from without and the formation of a single opening for urine drainage communicating directly with the bladder often leads to a speedy recovery in these instances

4 In cases of stricture with extravasation of urine The division of the former with direct drainage of the urine from the bladder as well as from the surrounding tissues is a matter for separate consideration

5 In some rare cases of wounds connected with the treatment of stricture which are rapidly followed by acute symptoms of impending death I had occasion to perform Holt's operation for a man with a chronic stricture The operation was apparently safely accomplished Some six ounces of urine were voluntarily passed 12 hours afterwards, when the patient had a severe rigor and was much collapsed With the exception of a few drachms no more urine was passed, and 24 hours after the operation a second rigor occurred with a temperature of 105° F Acting upon the opinion which I had formed that this patient was poisoned by something that was being absorbed through the urethral wound and that another dose would probably kill him outright I performed an external urethrotomy and put a large drainage tube into the bladder The patient had no further rigor, free excretion of urine followed, and he made a good recovery I am sure the latter was entirely due to the course that was adopted Another instance of acute suppression of urine which I saw in consultation under somewhat similar circumstances was dealt with in the same way equally satisfactorily Had death occurred in either of these cases, as seemed probable, there was no reason to believe that renal disease would have been discovered other than the congestion which is invariably found in instances of this kind and which is probably directly due to the poison that is absorbed

The points to which I attach importance in the operation of external urethrotomy are these (1) the use of a guide, (2) the utility of internal urethrotomy as an immediate preliminary to the external operation, and (3) the more efficient provision for urine and wound drainage

1 External urethrotomy when performed without a guide, so far as the stricture is concerned, is seldom anything else than a difficult, a dangerous, and an incomplete operation Fortunately, now it may be said that there is little or no necessity for making an attempt under such adverse circumstances So long as the canal is capable of transmitting urine even in minute quantities there is evidence as to its permeability, or, as Syme put it, "if the urine is permitted to pass no matter in how small a stream, there must be room for the introduction of an instrument provided it is sufficiently small and properly guided," An impervious stricture necessarily means the presence of a urinary fistula behind the point of obstruction If such conclusions could have been formulated in Syme's time how much more are they applicable now when we consider the great improvements that have taken place in all kinds of instruments used for this purpose But cases do occur, though much more rarely than formerly, where it is found impossible by reason of the character of the stricture to enter the bladder with a urethrotomy guide or ordinary staff Wheelhouse's method of dealing with an impassable stricture, though affording conclusive evidence of the permeability of all strictures not complicated with a urinary fistula will be found to furnish a solution to the difficulty Thus an external urethrotomy may be completed as perfectly as if an ordinary grooved staff were used Hence it may be concluded that no case of external urethrotomy for stricture should now be undertaken without the assistance of a guide, otherwise the chance of success is extremely remote The restoration of a structurally occluded urethra where the whole of the urine escapes through a fistula is another matter and will require separate consideration

2 The utility of an internal urethrotomy as an immediate preliminary to the external operation is shown by the ease and completeness with which the latter can be carried out or a larger staff than could otherwise be used

3 The necessity for providing the most efficient and cleanly kind of urine and wound drainage in connexion with external urethrotomy for stricture is apparent from what has been advanced The entire character of the tissue by which the stricture is repaired after it has been divided either in external or internal urethrotomy may be importantly determined by the nature and duration of the drainage and irrigation that is employed I am not aware that the influence of the latter on scar tissue which forms after lesions of the urine passages has ever been adequately considered from this standpoint I am glad to find that "the remote effects of surgical lesions of the urethra (*interventions sanglantes*)" have been selected for discussion at the Paris International Congress this year in the Surgical Section presided over by Professor Guyon, reports on this subject having been officially invited from Professor Albarran (Paris), Professor Marnochess (Odessa), and myself

In presenting these observations my objects are (1) to simplify, and to render more effectual the operations of urethrotomy, and (2) to substitute the least contractile and most pliable form of cicatrix or cicatricial interval for the original stricture

Lower Berkeley street W

THE MEDICAL EXAMINATION OF PERSONAL INJURY CLAIMS

BY ALBERT BENTHALL, F R C P EDIN, &C

OFTEN in the various phases of life there are questions which for a time do not come to the surface—questions which, though important to individuals or even to the body politic, do not appeal to the masses and yet are questions which eventually in the progression of an advancing civilisation have to be considered and answered

Twenty five years ago accident insurance companies were in their infancy, and the general public, although protected by the common law against accident occurring through the negligence or default of others, yet had not attained to the perception of its rights Since the advent of the school boards and the advance of general education with the increased knowledge and sharp wittedness of the population the individual members of the public have come to a full perception of their powers of claiming for disability, and a certain section have even advanced to a very exaggerated notion of the damages that may be obtained as compensation for the most trivial accidental injury The general public even if not employers are now liable to be shot at by all sorts of exaggerated if not bogus, claims, and although the wisest way for all of us is to insure, yet it must be remembered that the reasonable settlement of *bonâ fide* claims is of interest to everybody, inasmuch that large settlements are not only injurious to the individuals having to pay them, but must increase the rates of insurance to those who are provident enough to insure Thus the settlement of personal injury claims assumes an importance which it has never done in the past, and is now a question which has come to the surface and must be faced in the interest of all who are in the position of those who "have" in contradistinction to those who "have not"

To give some slight idea of the enormous number of accidents occurring in our midst which produce personal injury I may mention that in 1898 in London alone 9865 persons were injured by accident, of whom 145 died, that in the same year 16 091 persons were injured by railway accidents of whom 1269 died, and that the Ocean Accident and Guarantee Corporation in the mere working of its employers indemnity department in the 18 months from July 1st 1898—when the Workmen's Compensation Act of 1897 came into force—had to deal with 60 000 injured persons and over 1000 fatal claims

It is not a question of the masses against the classes for the masses have money, or money's worth in their labour and no one individual of the masses is safe from expense and even ruin, if a claim is made against him for accidental injury through his negligence or want of reasonable care This being the case it will be to the general good if claims can be investigated and settled with the least possible expense and trouble to the parties concerned. This I have no doubt will be admitted by everyone, but as to the obtainment of this "consummation devoutly to be wish'd" there are many points in dispute, for the dead past is in conflict with the living present.

In the days now past to which I have alluded, the general public was but little affected by claims for personal injury and the great railway companies were practically the only bodies who habitually employed medical men to examine and report, and these medical men were not asked to do anything further; thus it came to be generally accepted by the profession, that the duty of a medical examiner was simply to report on the medical aspect of the claim which he was asked to examine and that all questions of settlement or assessment of damages were outside his province. In these days, however, everyone shot at by a claimant alleging personal injury has not the millions of a railway company at his back, and it has become absolutely necessary that these claims should be examined, assessed, and if possible settled on the lowest possible terms and with the least possible expenditure in expenses. To effect this the cumbrous procedure of sending every claim to a firm of solicitors, who would in due course instruct a medical man to report, upon which the matter would be considered and the client advised, and after days or weeks of delay an attempt to settle be made, has had to be given up. Up-to-date insurance societies, firms, and even railway companies who are not fossilised in their methods, are now dividing their claims into two categories, immediately after receipt and inquiry—*contentious* and *non-contentious*. The former claims are sent as before to solicitors, and the latter, in which liability is absolutely clear, are sent to a medical man with instructions to examine and if the injuries are *bonâ fide* to assess and to settle in consultation with the medical attendants of the claimants. This procedure is of the greatest advantage to all parties; the claimant gets promptly, money which is very often urgently needed, and he also gets an absolutely fair assessment of his possible length of disability from his own medical man, while the firm claimed on for its share of advantage gets a fair instead of an exaggerated assessment, and a total absence of all legal costs which sometimes in cases which are allowed to run on, even where there is no question of law, amount to more than the original claim. In spite, however, of the obvious advantages of assessment and amicable settlement of personal injury claims by medical men, still it is sometimes said that the majority of medical men have not fitted themselves for the requisite attention to business principles and the minor legal questions which must crop up in these negotiations; and there is some truth in this, but an increasingly large number of medical men are quite capable of dealing with any business matter and many are well versed in the law as affecting these claims, even when they have not qualified themselves as barristers-at-law or as solicitors, and the object of this paper is to call the attention of our younger medical men to the fact that in the future medical men will be increasingly called upon to deal with these matters, and that therefore they should become conversant with the common law, the Carriers' Acts, the Employers' Liability Act, and the Workmen's Compensation Act, and the decisions governing them, and also that they should take care to train themselves in strict business habits.

Having devoted my time for many years almost exclusively to the examination of personal injury claims under the various Acts under which they can be made, it may not be considered out of place if I venture to state some of the principles which, in my opinion, should control the action of medical men in carrying out the further duties which the time and the age are casting on their shoulders. Although some of these will be mere obvious axioms to the members of the honourable profession which I am privileged to address through the influential columns of THE LANCET, yet I do not omit them as it might perchance be thought that I had not borne them in mind or considered them of the first importance.

The medical examiner should approach the consideration of each claim with a strong sense of absolute impartiality and fairness and he should never allow any discourtesy or even rudeness on the part of an illiterate or vulgar claimant to have any effect upon his mind or opinion, or to produce the slightest deviation from a demeanour of studied courtesy and sympathy.

I would especially call the attention of young medical men to the danger of either magnifying or minimising the effects of personal injury in a medical report—it must be remembered that on the medical report the question of settlement or of an action at law frequently depends, and that if the latter is decided on, every medical point or opinion given in the original medical report will have to stand the test of cross-examination in the witness-box. It is not only most humiliating and distasteful to be humbled in court, but it is fatal to the medical witness's chance of future employment.

He should, even in the most exaggerated claims, show no feeling or allow his temper to be in the slightest degree ruffled. He should always examine the claimant in the presence of his medical attendant and he should be studiously careful not to give pain in any tactual manipulation, as nothing will be more likely to make a claimant obstinate and angry than any suggestion of roughness in the demeanour of the medical examiner. All dressings, splints, or bandages should be removed and replaced by the usual medical attendant, and this for obvious reasons: first, because the examiner has no right to interfere with or influence the treatment, and, secondly, because if he should do so the claimant will have the power of alleging that the action of the examiner has retarded his recovery and thus increased his claim for compensation. The medical attendant should be treated with the greatest courtesy and consideration and nothing should be said in the presence of the patient likely to give the least offence; at the private consultation afterwards much may be said tactfully without causing the least friction.

All appointments and negotiations should go through the attending medical man or also through the solicitor where a solicitor has been instructed by the claimant; in this latter case an amicable and advantageous settlement can usually be obtained at a consultation at which the claimant's solicitor is present. I cannot sufficiently express my opinion that on no consideration should a medical examiner in any way even appear to go behind the back of the medical man attending or of a solicitor acting for the claimant—it is not only unprofessional, but any such attempt will recoil with tenfold force not only on the medical examiner, but on the firm for which he acts. Sometimes medical men are asked to examine and to arrange a settlement and are not informed that a solicitor has been consulted. I think the medical attendant should always be asked as to whether a solicitor has been instructed—as a settlement arrived at with great trouble may be upset and the matter reopened if a solicitor is ignored.

In such a complex civilisation as ours opinions must at times differ, even between professional men of standing and experience, but the more medical men I meet in consultation the more I am convinced that consideration and tact, careful examination of views opposed to one's own, with equally careful exposition of the reasons on which a conclusion has been arrived at, will clear away difficulties and produce a near approach to, if not an actual, harmony of view, and this is most desirable, for nothing gives so much occasion for the laity to scoff at professional opinion as the unfortunate disagreement on questions of fact which is sometimes apparent in the law courts.

The examiner's opinion should be held firmly, but it should be based on the solid foundation of fact and pure reason, and when this is the case it is soon felt that it is useless to oppose it.

In conclusion, I should like it to be emphasised that the medical profession cannot be enlisted for the purpose of making sharp settlements. Such an attempt would justly lead to strong remonstrance, but the profession by its position can legitimately and rightly be engaged by the public in the fair and impartial assessment of claims for personal injury where liability has to be admitted and there is no legal question except the amount which the claimants are entitled to under the Acts under which they claim. By courtesy and tact such claims can be settled by the medical attendant and the medical examiner meeting in consultation, to the mutual benefit of the claimant and the person claimed upon, and I feel sure that our profession, which is always so entirely at the service of the public, will in this matter uphold its honourable name and gain even more goodwill from those who depend upon its skill and impartiality.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

UNUSUAL ENDING OF A CASE OF EMPYEMA

BY JOHN CROPPER, M A , M B , B C CANTAB ,

LATE OF ACRE, PALESTINE,

THE following case is interesting from its rarity On Oct 20th, 1898, an Arab boy, three years of age, living in Acre, was brought to me by Dr Doukakis of that place with a history of illness of 19 days duration, the symptoms pointing to empyema of the right side of the chest On examination I found amongst other symptoms some bulging of the right side of the chest, together with absolute dulness of the lung below the level of the fifth rib, and the diagnosis was at once confirmed by exploration in the eighth intercostal space, where pus was found I therefore decided to open the chest next day and the parents consented to return with the child On bringing him to the hospital, however, the mother volunteered the statement that during the night a large quantity of pus had been passed by the bowel, and the truth of this was shown by the fact that the most prominent symptoms of empyema had disappeared, the right chest being resonant in its whole extent However, having confirmed the diagnosis the day previously, I held a consultation with Mr W H Anderson of Safed and decided to open the chest, the patient being in fairly good condition With the help of Mr Anderson, therefore, who administered chloroform, the chest was opened and one inch of the seventh rib was excised a little behind the mid-axillary line The point of exit of the pus could not be found with the probe and no long search was made A drainage-tube with flange was inserted after a small amount of pus had been evacuated and the patient was sent back to bed At the first dressing we found a little food on the gauze used and subsequently, though the pus decreased in amount, there was an abundance of clear, colourless, watery fluid, evidently gastric juice, with a few clots of milk on the dressings On Oct 24th, on illuminating the pleural cavity, watery fluid could be seen to be slowly oozing from the direction of the stomach, and from this time all food continued to come through to the dressings, and as it was found impossible to prevent this the patient got gradually worse He was taken home by his parents and died two days later It was of no use to ask for a post-mortem examination, this being invariably refused, for the moment death has occurred the house is always filled by relatives and friends who come to shriek over the body

Though empyemata are stated to burst in various directions internally I have not been able to find an account of one opening into the stomach (or duodenum), which evidently took place in this case Probably the operation made no difference to the result of the case, but doubtless it was put down as the cause of death by the parents who were Moslems Nutrient enemata were suggested and tried, but without effect as they were not retained Seeing that the child had had food on the day that he was brought to me there seemed no great reason for haste in opening the chest

Chepstow

A LOOSE FOREIGN BODY IN A HYDROCELE SAC

BY J R BENSON, F R C S ENG ,

LATE SURGICAL REGISTRAR KING'S COLLEGE HOSPITAL.

A BOY, 14 years of age was brought to me on Feb 1st, 1900, complaining of a lump in the left scrotum He was a healthy boy, but had hitherto been unable to join in ordinary games on account of the swelling, the sense of weight, and the fear of further injury to the left testicle The swelling had never been larger than it then was nor had the patient observed any variation in size He had consulted several medical men in London and Plymouth and had had fluid drawn out on three occasions Although this operation gave him relief his condition soon became as bad as ever Upon examination a hydrocele of about the size of a golf ball could be detected It affected the cord only and was quite free of the coverings of the testicle The testicle felt normal Owing to the flaccidity of the tumour and the rapidity of its return after operation I concluded that there was some communication with the general peritoneal cavity, although no impulse could be felt on coughing, nor did prolonged pressure bring about any reduction in its size or decrease in tension I advised complete removal of the sac and took the patient into my house for the performance of the operation A curved incision was made over the external ring and the cord and the testicle were drawn out of this incision The coverings of the sac were stripped off and the sac itself was freed from connexion with the cord The small fibrous band connecting it with the testicle was ligatured and tied The funicular process was not completely obliterated above, so I ligatured this neck in two places and cut between them and so removed the cyst unbroken The upper part of the funicular process communicated with the abdominal cavity by a long and very small canal, through which a fine probe could with difficulty be passed This process was treated as an ordinary hernial sac A stitch was passed so as to reduce the size of the opening in the abdominal parietes and the skin wound was closed The patient made an uninterrupted recovery, the dressings being left off on the eighth day

On examining the removed cyst a body of about the size and shape of an almond could be seen by transmitted light moving about freely within it The sac was opened and about an ounce or more of quite clear fluid escaped The foreign body proved to be a small mass of hard fatty tissue The outer part was somewhat looser in texture, very uneven and somewhat nodular The central part was more dense and fibrous—in some places almost cartilaginous There was no sign anywhere of its having been recently attached How did it get there? It may probably have been a detached piece of an appendix epiploica but if so it must have been very small when it got through the minute canal leading to the sac I could not find any history of the hydrocele having at any time been freely connected with the abdomen—in fact, it came very gradually and was first noticed below and only attained its present size within the last year or eighteen months Of course, it may have arisen from a little clot of fibrin after one of the previous tapping operations I have never seen a case before, though I find that Rose and Carless in their recent work make some mention of similar bodies in the hernial sacs The specimen which was a very perfect one, was, I am sorry to say, thrown away by accident after I had completed my examination

UNIVERSITY COLLEGE HOSPITAL

A CASE OF TRAUMATIC ENOPHTHALMOS

(Under the care of Mr PERCY FLEMMING)

A GIRL, aged 12 years attended at the eye department of University College Hospital on Dec 13th, 1899, with the history that two months previously she had been knocked down by a cart She was carried home, though she thinks she could have walked There was a wound on the left eyebrow and the eyelid and face were much swollen on that side The wound was stitched and the eye was bandaged There was also some bleeding from the nose When the eye was uncovered three days later, the child at once complained that she saw double, and the mother noticed that the eye was sunken Dr W W Hodgins, who treated the case at that time states that the wound healed by first intention and that at no time was there any sign of orbital cellulitis

The patient was taken to the hospital later on account of the diplopia.

The present state of the patient is as follows There is a linear scar about one and a half inches long extending inwards from the left external angular process of the frontal bone parallel with and just above the orbital margin. It is not adherent to the bone or puckered. The left eye is sunken, having much the appearance of an artificial eye. The left palpebral aperture measures nine millimetres in its widest part, while on the right side the measurement is 14 millimetres. The eye can be moved freely in all directions except downwards. The left pupil measures five millimetres, does not react to light, but reacts readily to accommodation. Cocaine causes a slight increase in the size of the left pupil, but no widening of the fissure. The right pupil measures 7 5 millimetres and reacts normally to light and to accommodation. The vision in each eye is $\frac{6}{6}$ and J. 1. There is crossed diplopia in the lower part of the field increasing in the downward direction, the vertical displacement being most marked when the patient looks downwards and to the left; the lower image belongs to the left eye. Tactile sensation over the lids, side of the nose, face, and conjunctiva is normal. While the patient was being tested for tactile sensibility she stated that some days after the accident she had noticed that the left side of the nose and face was numbed, and that she did not have any sensation when she touched the skin of those parts. The general condition of the child is very good and she seems to be in no way the worse for the accident with the exception of the eye symptoms. There are no signs of injury anywhere else than in the orbit.

Remarks by MR. PERCY FLEMMING.—Cases of enophthalmos fall mainly into two groups—the traumatic and the non-traumatic. Excluding more rare cases in which the eyeballs appear to sink in the orbit as the result of some rapidly exhausting illness such as cholera, the non-traumatic cases appear to be due to some lesion of the sympathetic fibres which supply the involuntary muscle in the lids and orbit, the enophthalmos being associated with a small pupil and a narrowed palpebral fissure. These fibres may be interrupted in different parts of their course. Thus the cord of the cervical sympathetic may be affected and Nicati records a case of retraction of the eyeball with myosis and ptosis associated with hypertrophy of the thyroid. Secondly, they may be affected as they leave the spinal cord. Experimentally enophthalmos has been produced by section of the eighth cervical and first dorsal nerve roots, and clinically cases of lesion involving the brachial plexus have been recorded associated with ptosis and myosis on the same side, though enophthalmos does not seem to have been observed, but a case was reported in THE LANCET of March 10th, 1900, p. 692, in which the brachial plexus was torn, and there was slight enophthalmos on the affected side with some narrowing of the palpebral fissure. Further, the path may be interrupted within the spinal cord by localised lesions such as are found in progressive muscular atrophy and syringomyelia, and although enophthalmos does not seem to have been noted in these conditions, yet the fact that myosis and ptosis have been observed makes it probable that a certain amount of recession of the globe may be present if looked for. In another group of non-traumatic cases the enophthalmos occurs in association with some affection of the fifth nerve. Thus a case has been recorded of morphœa[1] in the territory of the fifth nerve with enophthalmos and another in which the fifth nerve was involved in a pontine lesion,[2] and the condition is found, too, in cases of facial hemiatrophy. Another group of cases contains those in which the sunken eyeball becomes prominent when the patient stoops or when the internal jugular vein is compressed. Such cases have been explained as due to a vascular growth in the orbit, causing absorption of orbital fat, the vessels of the growth becoming engorged on stooping. In some of the cases in this group there is a history of preceding injury.

Several cases of enophthalmos following directly on injury have now been recorded. Various explanations have been offered and it is not likely that the pathology is the same in all cases. In some the cause is a definite injury of the sympathetic nerve. Thus a case is reported by Jacobsohn[3] of enophthalmos with ptosis and myosis after opening and scraping an abscess in the neck—the pupil in this case did not react to cocaine and only dilated slightly when the eye was shaded. Schrapinger records a case coming on two hours after an injury to the temple in which the condition of enophthalmos had disappeared completely in two days, and argues from the transitory nature of the symptoms that the lesion must be situated in the sympathetic, possibly, as he suggests, a hæmorrhage into the sympathetic root of the ciliary ganglion. In a second group of cases the explanation is to be sought for in a depressed fracture of the orbital wall, by which the cavity is enlarged and the globe sinks in as a consequence of atmospheric pressure. Lang,[4] in suggesting this explanation, referred to two extreme cases in which, as the result of an injury by a cow's horn, the eyeball was driven into the maxillary antrum. Fuchs[5] records a case of left-sided enophthalmos following an injury by a stag, in which there were paralysis of the left inferior oblique muscle and a small pupil, and he thinks that it is to be explained as a result of a fracture. Neulen[6] records another case which he considers to be due to a fracture, as the lower orbital margin showed a deep depression. A third explanation suggested for these traumatic cases is that the enophthalmos is due to an orbital cellulitis, the result of a penetrating injury—this acting either by causing direct traction on the globe as the inflammatory exudation contracts, or by causing a shrinkage in the orbital fat and in consequence an increase in the size of the orbital cavity with backward displacement of the globe as in the fracture cases. It is obvious that in any one case two or more of these factors may be combined; thus fracture may be associated with cellulitis and direct damage to the muscles as in a case reported by Löw,[7] and Beer has suggested that the orbital tissue may atrophy in consequence of a lesion of the fifth or sympathetic nerve. The diplopia in these cases may be ascribed to damage to one particular muscle as in Fuchs's case, and probably in the present one, or to interference with the proper movements of the globe as a result of the cellulitis; or again, it may be a mechanical result of the misplaced eyeball.

In the present case it seems quite possible from the completeness of the history to exclude an orbital cellulitis as the cause. And, on the other hand, the occurrence of epistaxis, the history of numbness over the cheek and nose, and the implication of the inferior rectus muscle are all suggestive of a fracture involving the floor of the orbit. It is difficult to explain the condition of the pupil; the myosis may possibly be due to some damage to the sympathetic in the orbit, but the reaction to cocaine shows that such damage cannot have completely destroyed the nerve.

ROTHERHAM HOSPITAL.

A CASE OF MENINGITIS FOLLOWING ENUCLEATION OF THE EYEBALL.

(Under the care of MR. F. B. JUDGE BALDWIN.)

MENINGITIS may arise in one of two ways from suppuration in the eyeball or in the orbital contents. The sepsis may spread through the lymphatic spaces which are well marked in the orbit or it may pass along one or more of the numerous branches of the ophthalmic veins. In the latter case a septic thrombosis of the cavernous sinus usually occurs. This dangerous complication of a wound of the eyeball is exceedingly rare at the present time, but even before the introduction of antiseptics it was not common. Mr. Nettleship in 1886 collected[1] 35 cases of meningitis following excision and those were all that had been recorded up to that date. For the notes of the case we are indebted to Dr. *J. Sackville Martin, house surgeon.*

The patient, a man aged 31 years, worked at a waggon builders and on Jan. 25th, 1900, he was standing about ten yards away from a running belt. A small brass clip, used to keep the belt in position, was detached and flew across striking him on the right eye. He was sent to Rotherham Hospital and was admitted. There was a Y-shaped wound in the cornea, the fork being uppermost. The iris was prolapsed and there was loss of aqueous. The prolapsed iris was removed. The eye was bathed with a solution of chinosol and a drop of atropine was put in. During the next three or four days the eye became inflamed. The conjunctiva was reddened and chemosed. On Jan. 30th there was a little pus between the edges of the corneal wound and a small amount was diffused in the anterior chamber. As far as could be seen the vitreous was quite clear.

On account of the severe headache suffered by the patient, as well as on considerations relating to sympathetic ophthalmia, it was decided to remove the eye. The danger of meningitis was considered and discounted as the suppuration present was so small in amount and so limited in its area. With Mr. Baldwin's consent, Dr. Martin removed the eye. The globe came out easily save at the last moment, when cutting the optic nerve the corneal wound gaped and the vitreous escaped. The vitreous was quite clear and examination of the posterior chamber showed no signs of suppuration. All antiseptic precautions had been taken. The instruments were sterilised in absolute alcohol and the socket was well douched with 1 in 1000 biniodide of mercury and dusted with iodoform.

On the morning of the day after the operation the patient was well and cheerful. Dr. Martin dressed the eye which was looking well. In the afternoon the ward sister noticed that the patient looked strange and was inclined to be restless. He shivered at times but had no definite rigor. At 4 45 P.M. the temperature was taken and was found to be 103° F. Dr. Martin saw him about 7 P.M. and he was then unconscious and could not be roused. He lay on his left side with the limbs flexed and rigid. He was sweating profusely and from time to time he put his hand to the back of his neck. At 9 P.M. he was still unconscious. The temperature was 104° and the pulse was soft and numbered 60. The pupil of the left eye was small and reacted sluggishly to light. He still perspired. There was no vomiting. From time to time he scratched the bedclothes with his fingers, using his hand like a claw. The respirations were 40. He remained unconscious all the night At 8 A.M. he answered to his name and complained of headache. He soon relapsed into unconsciousness, which continued all that day (Feb. 2nd), and he died on the 3rd at 3 30 A.M.

Necropsy.—On post-mortem examination the tissues of the stump were seen to be healthy and though the prolongation of the membranes was carefully dissected off the optic nerve no signs of suppuration could be found there. A layer of yellow pus lay along the right optic tract under the arachnoid. Pus was also found on the under surface of the pons and cerebellum and on the outer and inner surfaces of the hemispheres of the brain, being most abundant over the frontal and parietal areas on the right side. All the membranes were deeply congested, as was also the cortex of the brain. There were numerous puncta cruenta.

Remarks by Dr. MARTIN.—The above complication of enucleation of the globe is fortunately rare. When it does occur its results are so disastrous that no apology is needed [illegible]ng such a case before the readers of THE LANCET. [illegible]ty of such an occurrence should always be kept [illegible] The lesson to be learned from this case would [illegible]e the necessity for extreme caution in enucleating [illegible]hich there is any evidence of active suppuration [illegible]w slight its amount. An eye as severely injured [illegible]vas should have been enucleated at once, and this [illegible]e been done had it been possible to have obtained [illegible]tient's consent. In the light of the experience [illegible]ned in this case it would have been preferable to have [illegible]owed the eye to pass through a condition of panophthalmitis to phthisis bulbi, when it could then have been removed with less danger. The case is a painful one, but its instructive value is so high that I have no hesitation in recording it. I am indebted to the kindness of Mr. Baldwin under whose care the case was for permission to do so.

A LARGE BEQUEST TO LONDON HOSPITALS.—Four London hospitals will benefit by a sum estimated at between £300,000 and £400,000 under the will of the late Professor David Edward Hughes, F R S. The first trustees of the "David E. Hughes Hospital Trust Fund" are to be the treasurers of Middlesex Hospital, London Hospital, King's College Hospital, and Charing Cross Hospital, who are to retain the capital of the fund under certain conditions. The will expresses the wish that after a period of 21 years the four hospitals will add to their respective funds as capital one-third of their income from Professor Hughes' bequest.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Skin Affections in Bright's Disease.

A MEETING of this society was held on March 13th, Dr. F. W. PAVY, the President, being in the chair.

Dr. HUGH THURSFIELD read a paper on the Skin Affections met with in Bright's Disease. After carefully comparing the accounts of all the writers whom he had been able to consult he suggested the following classification: 1. The affections which characterised the early stages of renal disease: pruritus, urticaria, and eczema. 2. Those which occurred in the final stage and in uræmic conditions: the universal erythematous, bullous, or desquamative eruptions. 3. Purpura and other hæmorrhagic eruptions. 4. Those affections which were seen only with marked œdema and which were in all cases, he believed, due to a local infection of the skin, usually by some one of the pyogenic micrococci. Of these last he did not propose to say anything on the present occasion. 1. In 1874 Rosenstein drew attention to the occurrence of intolerable itching, without any rash or inflammation, in chronic uræmic conditions. Ten years later Bartels confirmed these observations and at the same time showed that aggravated pruritus was not infrequently an immediate antecedent to uræmic convulsions. Besides the cases which occurred in advanced stages of the disease there were others in which the pruritus made its appearance as an early symptom, perhaps the only one which was so regarded by the patient. In addition to a case which he quoted he had twice seen pruritus in cases of chronic nephritis, where it was the only symptom for which the patients demanded treatment; in one of these cases it preceded the onset of uræmic convulsions on several occasions. Urticaria as a complication of Bright's disease was probably less well recognised than was pruritus. Dr. H. Waldo of Clifton had reported a case of acute nephritis with uræmia attended by an urticarial rash which lasted for a week and was followed by desquamation. The patient recovered. Eczema had for long been regarded as a disease which had a close relation to failure of the excretory functions; but although most writers on skin diseases enumerated Bright's disease among the causes of eczema there was nothing in his opinion to show that eczema was more common in patients suffering from albuminuria than in others. 2. The second group of skin affections were those which occurred in the later stages of Bright's [illegible] and which consisted principally of generalise[illegible] were [illegible] Of these one in particular had attracted a [illegible] attention—viz., "erythema papulatum [illegible] on Coxa Vara. Hervers described an eruption, consisti[illegible] in five of these [illegible] of a bright red colour, which [illegible] of coxa vara, and th[illegible] and at the end of a few days the m[illegible]without the Roentgen ra[illegible]me confluent and occupied the whole[illegible] be possible to fi[illegible]he face. Then either desquamation took[illegible]gan between 10 and[illegible] of small branny flakes (Huet) or in [illegible]xcepting one. C[illegible] almost equalling in size those of derma[illegible]ty of the upper e[illegible]ancaster). All agreed that the eruption app[illegible]k below the i[illegible]ediate precursor of uræmic symptoms, and the [illegible]arance of this rash was an omen of the utmost gravity; the [illegible]ongest period which ensued from the appearance of the rash till the death of the patient was five weeks. Dr. Lindley Scott in the *British Journal of Dermatology* for July, 1899, reported five cases and observed that erythema papulatum uræmicum was a rare disease. Dr. Thursfield had been able only to find in all 46 recorded cases in the medical literature of the last 25 years. The generalised bullous eruptions were, however, still rarer in chronic nephritis. In 1867 Dr. Murchison reported a case of chronic pemphigus which terminated in death by uræmia. General exfoliating eruptions had only lately been recorded in kidney disease. Dr. Pye-Smith in 1896 stated that he had twice seen an eruption resembling a universal pityriasis rubra, remarking that the eruption appeared as a late symptom when other features of Bright's disease were already prominent. Dr. Thursfield narrated two cases which raised the question whether renal disease might not be a cause of general pityriasis rubra which was sometimes overlooked. Altogether he had found records of eight cases of universal exfoliative dermatitis in chronic Bright's disease, including one doubtful one. 3. The third division which he had proposed included purpura and other hæmorrhagic affections. The chief interest of these lay perhaps on the historical side. In 1813 Blackall, a physician of Exeter, published a remarkable book on the "Nature and Cure of Dropsies," and he described four cases resembling "land scurvy." In reading his account it seemed certain that these were purpuric eruptions occurring in the course of Bright's disease. In 1849 Walshe recorded a case of Bright's disease with a hæmorrhagic eruption. Dr. Gee recorded the cases of three children, all of whom had purpura associated with chronic nephritis; and lastly, at a meeting of the Clinical Society in May, 1889, Dr. Colcott Fox reported a case of hæmorrhagic erythema occurring in an elderly woman the subject of granular disease of the kidneys. As to the causation of all these different forms of skin affections in Bright's disease the most probable suggestion appeared to be that they were due to some special toxin or toxins circulating in the blood. They thus came into close relationship with the rashes which occurred in septicæmia and in connexion with certain drugs, and, as in these instances, the toxin most probably acted, not directly, but through the agency of the vaso-motor and trophic nerves. The nature of the toxin was absolutely unknown, though it was certain that it was neither urea nor uric acid. Possibly it might be not merely one well-defined substance, but the product of several toxins interacting on one another.

Dr. PYE-SMITH congratulated Dr. Thursfield on his paper and remarked on the rarity of eruptions of the skin due to disease of kidneys. Moreover, it did not follow that when two phenomena co-existed they were necessarily causally connected. He was not at all satisfied that eczema was ever really due to Bright's disease, though it was not surprising to find two common affections like these together. As regards erythema læve (Bateman) there was no doubt that it was associated with acute Bright's disease. This was a more or less local condition and of inflammatory origin. Other skin affections were associated with chronic renal disease. He agreed with Dr. Thursfield in putting aside the purpuric conditions; these were only part of the general tendency to hæmorrhage. Pityriasis rubra had a definite relation with renal disease. Some observers might regard the renal disease as most likely secondary, but the skin affection was the result of the kidney disease. The most common eruption in his experience was an eruption consisting of large discrete papules with considerable pruritus. This was the skin lesion which had the closest relation to chronic renal disease and he narrated cases in illustration in which marked pruritus was a feature. In many cases the patients did get better of these eruptions, and it was not correct to call them uræmic, for they appe[illegible] before the uræmic stage. He did not share the views [illegible] that these eruptions had such a lethal tenden[illegible], the prognosis was not any worse for the prese[illegible]on. The renal affection was of itself seriou[illegible] stages were more often attended by ski[illegible]er stages.

Dr [illegible] marked that there were two ways o[illegible]n—either the renal disease as the caus[illegible] the skin lesion as the cause of the albu[illegible] not from his experience say that an[illegible]er of skin disease necessarily suggested [illegible]. It was only by the complete inve[illegible] the organs in any given case of skin d[illegible] their renal origin could be discovered. [illegible] was associated sometimes with albuminuria, but [illegible] far more often associated with glycosuria. Some cases o[illegible]riasis rubra did occur with albuminuria, but he believ[illegible]at albuminuria was more often a late sequel of the [illegible] affection than *vice versâ*. He did not think that derm[illegible]s herpetiformis had much to do with renal disease—[illegible]was rather in his opinion a neurosis. Uræmic erythema was undoubtedly connected with renal disease. In these circumstances he had often noticed that the occurrence of the erythema in the shape of discs was suggestive of a uræmic origin and he quoted cases in illustration. A woman, aged 34 years, who had albuminuria, developed an eruption of this kind. The skin at first got better, but later it developed into a generalised lupus erythematosus and she died. He also mentioned the case of a boy, aged 12 years, in whom the skin lesion began as a papular erythema which coalesced and became diffuse. In this case the kidney was a large white kidney. He believed any form of renal affection might give rise to these skin symptoms and many varied kinds of skin lesion might be associated with renal disease. Skin disease might be due to many different toxic causes and the same cause might give rise to different forms of skin disease.

Dr. SIDNEY RINGER said that he would like to ask whether the skin disease could be produced indirectly through the nervous system by modifying the action of some microbe. Might it not be due to a direct action? The influence of the nervous system could be seen in infectious fevers, such as chicken-pox, and herpes zoster was another well-known illustration.

Dr. H. A. CALEY thought that there was no doubt that exfoliative dermatitis was sometimes directly due to renal disease. Some years ago in the wards of St. Mary's Hospital there was a remarkable series of cases of exfoliative dermatitis, and the proportion of cases in which it was associated with Bright's disease was too large for any casual connexion. The form of the renal disease in all was chronic interstitial nephritis.

The PRESIDENT remarked that in view of the close relation between the skin and the kidneys it was surprising that skin complications were not more often met with in chronic Bright's disease. Moreover, the complications of chronic Bright's disease affected the surface structures, such as the serous and mucous membranes. The poison of chronic Bright's disease also ought, it would seem, to affect the nervous system and through it the skin. The nature of this toxin was very obscure. It was due to an arrest of the function of the kidney, but not only this, an altered metabolism occurred in the body, and this was what constituted uræmia. The dyscrasia which resulted was manifested in some forms of skin affections.

Dr. THURSFIELD, in his reply, remarked that he regarded erythema læve as one of the diseases which affected tense œdematous skin and belonged to the fourth group of diseases which he had not discussed in his paper. The universal eruptions seemed always to be associated with chronic interstitial nephritis, excepting only in one case which he narrated. But in most cases it was the granular kidney which was associated with these skin affections. As to the question whether the albuminuria might not be the consequence rather than the cause of the skin affection, it was a most remarkable fact how seldom even severe cases of skin affections were complicated by albuminuria.

MEDICAL SOCIETY OF LONDON.

A New Method of performing Prostatectomy.—Coxa Vara.

A MEETING of this society was held on March 12th, Dr. FREDERICK T. ROBERTS, the President, being in the chair.

Mr. P. J. FREYER read a paper on a New Method of performing Perineal Prostatectomy. He commenced by expressing the opinion that the vast majority of cases of senile enlargement of the prostate were best treated by careful, cleanly, and judicious catheterisation; but there were a minority in which some kind of operation was advisable, and a still smaller number in which it was imperative. The various recognised methods of performing prostatectomy might be classified into three groups: (*a*) Palliative operations, undertaken when the disease was complicated by severe cystitis or other conditions rendering catheterism impossible or extremely difficult: (1) suprapubic cystotomy with temporary or permanent drainage of urine through a retained tube; and (2) perineal urethrotomy with temporary or permanent drainage. (*b*) Operations undertaken for the purpose of inducing permanent atrophy or shrinkage of the enlarged prostate: (1) castration; and (2) vasectomy. (*c*) Radical operations, which aim at removing a part or the whole of the obstructing portion of the gland: (1) division of a median obstruction by means of the galvano-cautery, introduced through the urethra (Bottini) or through a perineal section (Wishard); (2) removal of a median growth through a perineal opening in the urethra by cutting forceps or other instrument; (3) suprapubic prostatectomy (commonly known as McGill's operation), suitable only for enlarged middle lobe, ring of hypertrophied tissue round the orifice of the urethra, or enlargements of the lateral lobes prominently projecting into the bladder; (4) perineal prostatectomy by Dittel's method, which consisted in removing a wedge-shaped portion from the under surface of one or both lateral lobes, through an incision extending from the median raphe round the sphincter ani to the tip of the coccyx, the urethra and bladder being left intact; and (5) Nicoll's operation, which was similar to this last, only that a preliminary suprapubic cystotomy was performed for the purpose of introducing a finger into the bladder, with a view to pushing the prostatic tumour into the perineal wound, thus facilitating its removal. In the operation about to be described advantage was taken of the perineal incision recommended by Dittel. The patient was a man, aged 59 years, who came under the care of Mr. Freyer in October, 1899, for the following symptoms: increased frequency of and difficulty in starting micturition, diminution of force, and sometimes intermittency of stream. For some months the urine had occasionally been dark-coloured and there was pain at the end of the penis and in the hypogastrium. All the symptoms were worse at night; they were increased by exercise and relieved by rest. No stone could be detected. On examination of the rectum a tumour of the right lobe of the prostate twice the size of a walnut could be felt, very tender to the touch. This was confirmed on examination by the cystoscope, and the tumour projected into the bladder. The first step in the operation was the performance of external urethrotomy in the usual way. The fingers introduced into the bladder detected a tumour of the right lobe of the prostate and by means of another finger introduced per rectum it could be felt as a rounded, hard, nodulated lump. It was then removed by the perineal method and the prostate was removed piecemeal. Bleeding was not profuse and no ligatures were necessary. A large soft rubber tube was inserted to drain off the urine direct into a vessel under the bed and the usual dressings were applied. The whole of the urine [illegible] through the tube during the first six days, but two weeks later the patient began to pass urine through the natural passage and the perineal wound healed soon afterwards. The patient made a good recovery and left the "home" Dec. 18th. The tumours turned out to be of a poison adenomatous type resembling that frequently found [illegible] in aged. The advantages claimed for this method of operation were: 1. The preliminary external urethrotomy permitted of the introduction of the finger into the bladder, which, with a finger in the rectum, enabled the surgeon to define accurately the shape, density, size, and extent of the prostatic growth in a manner that could not be otherwise accomplished, except, perhaps, by a suprapubic opening—a much more serious proceeding. 2. The finger could be hooked over the enlarged lateral lobe and this latter pushed well into the wound in the ischio-rectal fossa, thus to a large extent obviating a deep and dangerous dissection, as in Dittel's operation. 3. With the tumour pushed well into the wound the capsule could be easily incised and erased, and the cutting forceps and scissors easily and freely applied to eradicate the whole mass. 4. The finger in the bladder enabled the surgeon to feel where the cutting instruments were approaching that viscus so that he could remove the whole growth excepting a thin layer for the support of the mucous membrane of the bladder and prostatic urethra without opening the latter, thus avoiding infection of the wound and the existence of a permanent fistula. 5. The large perineal drainage-tube inserted into the urethral wound carried off all the urine and prevented the perineal wound from becoming septic. The drawback to this operation was that, like all other operations proposed for removal of prostatic growths, it was applicable only to certain forms of this disease. It was not, of course, applicable to cases of enlarged middle lobe projecting into the cavity of the bladdder. For such cases McGill's operation was undoubtedly the best. In very fat patients or when the prostatic tumour was extremely large it might not be feasible owing to the fact that the finger might not in such cases be sufficiently long to hook it round the growth.—Mr. C. W. MANSELL MOULLIN had always thought that the operation of prostatectomy had been kept rather in the background in spite of McGill's successes. It had never become very popular. There were, however, certain cases in which prostatectomy could be done with advantage. When there was any intravesical growth the operator could not get at the growth in such cases; and, again, if the perineum was very fat or very rigid a tumour was difficult to reach, but when the tumour was confined to an extravesical situation the operation could be done with comparative ease. Many failures were due to its being postponed too long when cystitis became established. He had about three months ago performed almost an identical operation as that described, though he had not, like Mr. Freyer, planned it beforehand; nor did he insert a tube for urine, as Mr. Freyer had done. The patient passed urine per urethram almost from the time of the operation. Nicoll's operation was much more thorough, but it involved a suprapubic incision, which was a serious disadvantage. He had only one criticism on Mr. Freyer's paper to offer: the symptoms had commenced when the patient was 56 years of age, and why should it be called "senile" enlargement?—Mr. SWINFORD EDWARDS wished also to take exception to the title of the paper. The operation should be spoken of as an operation by para-rectal incision combined with external urethrotomy. Mr. Freyer had not mentioned one operation which he (Mr. Edwards) had been in the habit of employing—viz., urethral prostatectomy with Woolley's prostatectome. No one method was applicable in all cases. Mr. Freyer's operation seemed suited for those cases where the tumour was limited to one side and of limited extent. For intravesical tumours he thought McGill's operation was the best.—Mr. STANLEY BOYD agreed with Mr. Swinford Edwards in his criticism on the title of the paper. He would also like to know what was the effect on the rectum and whether it had the result of anæsthetising the anus? Would it not be an advantage if a large semilunar flap were thrown backwards behind the scrotum exposing the central part of the perineum?—Mr. BRUCE CLARKE remarked that no prostatectomy was an ideal operation because the prostate might become enlarged in three directions, into the bladder, and into the rectum, and it might produce pressure on the prostatic urethra. His experience was that only temporary good was accomplished by such operations because sufficient could not be removed at one time. No one operation was suitable for all cases. The reason prostatectomy [illegible] not more often performed was because very nearly all of [illegible] were septic and because it was very difficult to know beforehand what was the extent and nature of growth to be removed.—The PRESIDENT remarked that these cases did not always go to the surgeon first. The point about cases becoming septic before operation was a very important one and he thought it would be well if a surgeon were called in before cystitis had supervened. He objected to cases being referred to as "senile" when the patient was only 60 years old or less.—Mr. FREYER, in reply, again pointed out that the operation suggested was only applicable to certain forms of prostatic growths—viz., lateral growths. He could not agree with Mr. Moullin that Nicoll's operation was the only one applicable when the growth projected into the bladder. In his case the tumour had projected in this direction. He was quite surprised that operation had not been thought of before. In describing the case as one of senile enlargement he followed Sir Henry Thompson. The objection to many of the other operations was that the operator was working in the dark. No two cases of prostatic disease were alike, and therefore different operations were called for.

Mr. C. B. KEETLEY read a paper on Coxa Vara. He had seen seven adolescent cases, and in five of these skiagrams had demonstrated the existence of coxa vara, and the other two were sufficiently marked without the Roentgen rays. By searching it would, he thought, be possible to find many others. The symptoms in all began between 10 and 16 years of age—i.e., about 14 years—excepting one. Coxa vara might be described as a deformity of the upper end of the femur. The head tended to sink below the level of the trochanter. There was considerable curvature of the neck of the femur. The articular surface of the head tended to look downward. It was not a mere shortening of the [illegible]. The shaft was also bent. The upper and the [illegible] parts of the neck were the strongest parts, [illegible] the [illegible] and outer, as in normal femora. Very often no evidence of rickets existed in any of the cases, but that was perhaps because the rachitic process was over. Genu valgum was often present also, and this indicated rickets. He believed that coxa vara was really often a compensatory deformity of genu valgum. Alteration of the bones of the face and forehead also often coexisted—at least, when coxa vara came on early in life. Pain in the hip, increased by walking, was almost always the first symptom noted; it often extended to the knee, and this caused cases to be mistaken for hip-joint disease. Soon after the patient began to limp and three or four months after this the opposite limb was affected. Objective signs appeared soon after, and with these there were shortening of the limb and some amount of genu showed more leucocytes than red blood discs. The subcutaneous tissue was mucoid, there were no structural differences between arteries and veins, and nucleated corpuscles, some containing hæmoglobin, were found in the bone marrow. In both specimens the thyroid, the spleen, the thymus, and the liver were absent. In the large fœtus the ovaries and rudimentary kidneys were present, and in the smaller fœtus the genito-urinary arrangement of a fifth-month fœtus was noticeable. These dropsical parasitic fœtuses were probably the result of an imperfect division of the ovum to form twins. It was known experimentally that absorption of part of a segmenting ovum led to such errors in development. A parasitic fœtus was probably the result of the unequal division of a twin-forming ovum.—The PRESIDENT said that he had published a communication on Acardiac Monsters in the Museums of London Medical Schools which was to be found in the Transactions of the Obstetrical Society of *London for 1889. He congratulated Mr. Keith on his lucid* demonstration of a very complicated teratological subject. Dr. Boxall's and Mr. Keith's two specimens caused practitioners to reflect on the precise significance of fœtal œdema and anasarca.

Dr JOHN PHILLIPS read a paper on a case of Extra-uterine Gestation in which Fœtal Death occurred at Term after Spurious Labour, and where Abdominal Section was performed from four to five months later The patient, aged 31 years, had had three children, the youngest nine years ago. She had menstruated last normally in November, 1896 (the exact date was uncertain). About a month later she was seized with severe abdominal pain and was ill for 14 days. Subsequently all the symptoms of a normal pregnancy developed; she had, however, frequent and prolonged attacks of pelvic and abdominal pain. At term a spurious labour occurred and subsequently the signs of pregnancy became less marked and the abdomen less distended. From four to five months afterwards she was seized with much pain and fever after a rigor. The abdomen was opened and a full-term dead fœtus was removed from an extra uterine sac. The placenta, which was putrid, was removed without hæmorrhage. The patient made a good recovery and was now in good health.—Dr. C. J. CULLINGWORTH commented upon the normal condition of the Fallopian tubes in this case. As tending to corroborate Mr. Bland Sutton's observations on the analogy between the behaviour of the uterus and the Fallopian tubes when expelling a contained ovum he had on a previous occasion exhibited to the society a Fallopian tube which had entirely resumed its normal appearance 10 hours after the occurrence of rupture and expulsion of an early ovum. He thought that Dr Phillips's theory was correct—viz., that there had been a complete tubal abortion and that the ovum had preserved its vitality and had continued to develop in the abdominal cavity. He thought that the fœtal sac would then be the fœtal membrane, but wished to know if it had been examined. He asked for further information as to the site of implantation of the placenta, and especially as to whether the placenta had retained its connexion, wholly or in part, with its original site, which was the general rule.—The PRESIDENT observed that his own case of removal of a putrid fœtus would shortly be reported. It was not "abdominal," but of the "posterior ligamentary" type, infection occurring through the walls of the rectum. The patient did well for six weeks and then she sank slowly from marasmus rather than from complete obstruction, dying in the ninth week He asked Dr. Phillips whence the putrid infection was derived in his case.—Dr. JOHN PHILLIPS, in reply, said that a piece of the sac wall had been excised and microscopically examined; it consisted of fibrous tissue. The colon was incorporated in the sac-walls and hence the putrefactive changes which took place.

Mr. G. W. B. LAWRENCE, introduced by Dr G. F. Blacker, gave a short demonstration on Spondylolisthesis.

The following cases and specimens were shown.—

Dr. BLACKER. Specimens illustrating Mr. Lawrence's demonstration on Spondylolisthesis.

Dr. MACNAUGHTON JONES: Two cases of Congenital Malformation of the Genital Organs.

Dr. LEWERS: (1) Rupture of the Uterus, with a Dermoid Cyst of the Ovary; and (2) Fibroid undergoing Mucoid Changes, Abdominal Hysterectomy.

Dr. CULLINGWORTH and Dr. J. S. FAIRBAIRN. An Acutely Inflamed Ovarian Cyst communicating with a Chronically Inflamed Fallopian Tube.

Dr. R BOXALL: Fœtus with Anarsaca and Large Placenta.

CHELSEA CLINICAL SOCIETY.

The Treatment of Rheumatism

A MEETING of this society was held in the Parish Hall, Pavilion-road, Chelsea, on March 13th, Mr. FOSTER PALMER being in the chair.

A discussion was opened by Dr. W. EWART, whose speech is printed in this issue of THE LANCET (see p. 761), upon the Treatment of Rheumatism, with special reference to Prophylaxis and its Cardiac Complications.

Dr. T. J. MACLAGAN said that if they wanted to
the pathogenesis of the disease they must go b
days when it was possible to study it b
cylates were introduced. In early times
ment was by bleeding and purgatives. Th
form of treatment was introduced by Sydenh
came the alkaline treatment with the sup
lactic acid was the cause. Next came the tr
William Gull by mint-water, but no form of t
controlled the disease. It struck him
to use salicin at the same time when
introduced into Germany. The rheumat
on the muscle and on the joints;
advanced was that the rheumatic poiso
origin, which, however, had never b
it was a minute organism acting on
on the fibrous textures of the joints. The salic
ment had an absolutely curative action. The heart
in the same position as the joints—what recovered i
joint recovered in the heart; the one structure whic
not apt to recover was the endocardial lining. He di
know on what grounds Dr. Ewart asserted that ca
complications were more frequent with the salicylate t
ment than before; he could not accept it without some
to support it and he called it into question at once. If the fact was accepted that salicylate treatment did control the rheumatic process it must have the same action on the cardiac complications as it had in the joints. Dr. Ewart had referred to the influence of cold; it was easy to put everything down to chill and cold and he could not agree with that view.

Dr. A. E. SANSOM considered that arthritis was one thing and that rheumatism was another, or, in other words, rheumatism was one thing and arthritism was another. He had seen the treatment by blisters, by big, little, and all sorts of blisters, and he concluded that it added nothing to the patient's ultimate recovery, but considerably to his discomfort. He thanked Dr. Maclagan for the salicin treatment because patients were now placed in a condition of comfort. He used salicylate of soda without combining it with alkalies in the first stages. There were so many difficulties about estimating the occurrence of heart lesions that it was taken out of the range of statistical inquiry. In acute rheumatism heart lesions might be very pronounced or untraceable and symptomless and unknown except for physical examination. He had seen pericarditis occur without any symptom at all in a boy who insisted upon walking about, and it was not possible to get him to rest in bed; he had unmistakeable pericarditis, they had to try to keep him quiet. He had not seen many cases in which there had been toxic symptoms from salicylate. He had known of cases in which it seemed that that must be so, but the evidences had shown that the toxic symptoms were really manifestations of the disease. He advocated the use of the ice-bag, as Dr. D. B. Lees applied it, in cases of rheumatic pericarditis. The process of rheumatic valvulitis was extremely slow and extremely subtle and care ought to be exercised in the prognosis and treatment. As regards rheumatic endocarditis they were very powerless indeed, but they had in their present methods of gradual muscular exercises, baths, and hygiene a means not possessed in the early days of the treatment of heart affections Galvanism might be tried to the vagus; the treatment required patience and produced no harmful effects. In the more acute stages of the development of cardiac disease he had seen a great deal of harm result from digitalis—very often it produced toxic effects without procuring the toning *up of the heart muscle; and the same objection applied when* there was the condition of swollen heart

Dr. DONALD HOOD said he was not satisfied from statistics that salicylates formed such a great remedy as many considered. From his investigations he found that the patients under salicylates were longer in hospitals, more generally enfeebled, and the complications seemed to be more formidable. It seemed to him that after the treatment with salicylate of soda patients suffered more from after crippling. They might be led astray by the fact of the great relief to pain from salicylates and forget the enormous number of patients who relapse after treatment. He had been for many years in the habit of giving patients what he would call a modified alkaline treatment.

Dr. D. B LEES said that the term cardiac complications ought not to be used any longer. Rheumatic heart disease was more important and more common than rheumatic inflammation of joints. Rheumatic fever should be spoken of as a cardiac disease with arthritic complications. In first attacks acute dilatation of the left ventricle was always present, in later attacks it was probably always present also. In many cases of chronic heart disease failure of compensation was not merely from damaged valves but from fresh rheumatism. He thought rheumatism was due to an undiscovered microbe, and it was highly probable that it was a house disease, and it seemed likely that its prevalence would be diminished if every house had an impermeable basement. In treatment long-continued rest was important and the ice-bag, which had yielded such striking results in pericarditis, might often be useful in rheumatic myocarditis.

Dr. A. E GARROD said the evidence seemed to him to suggest that rheumatism was a disease due to a micro-organism and if so its infection did not come to an end but lingered on In adults minor rheumatic attacks were seen, but a child would shew the evidence of the persistence of the infection for years. In post-mortem examinations of old heart cases there had been seen beads on the valves evidencing a fresh outbreak of endocarditis. The use of salicylates would not have become universal and lasted for 20 years unless there had been something in it; the effects of salicylate, however, were not, in his opinion, very marked on cardiac complications.

The meeting then adjourned to Tuesday, March 20th.

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on March 2nd, Dr. J. F. W. Silk, the President, being in the chair.—Dr. Dudley Buxton, in re-opening the adjourned discussion on the Respiratory After-effects following the Inhalation of Ether, said that there were three most important questions involved: (1) whether any respiratory after-effects could be entirely attributed to the use of ether; (2) if so, what was the pathogenesis of these complications; and (3) the question of prophylaxis. With regard to the first point he thought that the descriptions and names had been badly chosen because he did not believe that "ether pneumonia" was an entity or any special disease, and that many of the cases that had been reported were due to other probable influences that had been at work. An enormous amount of experimental work had been done abroad, especially in Germany, but the clinical research was less satisfactory, inasmuch as in most cases no reference was made to the method of administration of the anæsthetic. Incidentally he referred to the fact that a large number of cases of respiratory trouble had been recorded as following the inhalation of chloroform, and he pointed out that the trouble was seldom ascribed by surgeons to the chloroform itself, although it was a well established fact that that anæsthetic frequently caused such after-effects. With regard to the frequency with which respiratory troubles occurred after the use of ether, he had found it extremely difficult to prove that ether was the responsible factor, as the published statistics were very loosely recorded. For instance, one observer recorded 17 cases in 4914 administrations, but seven of these were pneumonias commencing on the seventh, twenty-fifth, fifth, fifth, fourteenth, tenth, and fourteenth days after the inhalation, and only two within 24 hours of the operation. It appeared to him at least probable that in these intervals of time many other factors would be at work. Further, the recorded cases had in almost all instances been hospital patients. On the other hand, Julliard of Geneva had never met with any lung complications in upwards of 4000 cases. His own experience was that lung complications were extremely rare, especially in private cases, and that the disease was of the ordinary catarrhal type, modified perhaps by the condition of the patient and the exigencies of the operation—e.g., tight bandaging. With regard to pathogenesis he referred to the important work of Hölscher, Whitney, and Lindemann, who ascribed the pneumonia to direct infection from the pneumococcus associated with the mucus from the mouth. He himself thought that in considering the pathogenesis it had generally been overlooked that the position of the patient under an anæsthetic was not that of the normal individual. For one thing the body temperature was lowered from 2° F. to 4°, which meant, of course, that the vitality and resisting power were correspondingly diminished. The other view was that the ether acted entirely as a local irritant to the bronchi and fine air-cells. In many cases no doubt initial lesions were overlooked. As to prophylaxis Dr. Buxton considered that the limitation of the amount of ether was of importance. When once the patient was fully under very little more ether should be given. All cyanosis should be avoided and the patient should be kept warm during the operation and not exposed to draughts afterwards. He did not think that there was much risk of infection through the face-pieces, though, of course, this should be kept clean —A letter was read from Mr. Carter Braine in which he expressed the opinion that pulmonary troubles after ether were extremely rare provided that the ether was properly given and in suitable cases. Out of 4380 cases of ether administration he had only met with one case of pneumonia, and he was doubtful whether in that one the ether could be entirely blamed, as the patient was exposed to draughts afterwards. Considering the amount of exposure to which patients were sometimes subjected he was rather surprised that pneumonia did not occur more frequently, and he advocated the judicious selection of cases and the substitution of chloroform if ether was found to disagree —A letter was also read from Mr. T. H. Pounds of Derby, who thought that the occasional cases of pneumonia after ether were due to the hyper secretion of mucus occluding the smaller bronchi, and advocating the early administration of belladonna or atropine.—Dr. E. M. Corner gave some interesting details of cases which had come under his notice as surgical registrar at St. Thomas's Hospital.—Mr. G. Eastes agreed with Dr. Dudley Buxton as to the rarity of the lung complications after the administration of ether, but referred to two cases—one of bronchitis and one of pneumonia after chloroform —Mr. W. E Burton only remembered one case out of certainly 4000 administrations in which any appreciable bronchial catarrh had followed the use of ether, but, on the other hand, he had seen many cases of bronchial catarrh after chloroform.—Dr. Probyn-Williams referred to two cases which occurred at the London Hospital in 1897. With regard to Professor Julliard's cases he mentioned that nearly all of the patients had a hypodermic injection of morphia before the administration of the ether. He agreed with the previous speakers as to the importance of changing to the A O.E mixture or chloroform if much mucus was secreted under ether.—Dr. G. B. Flux thought that possibly some cases of pulmonary trouble might be due to the inhalation of small quantities of liquid ether and to faulty administration —Mr. Walter Tyrrell believed that cases of bronchitis might sometimes be due to too rapid administration or too strong a dose of ether To get rid of the excessive amount of mucus he thought that it was occasionally of service to let the patient come round sufficiently to cough and retch.—Mr. H C. Crouch reported a case in which death associated with pulmonary complications occurred after the rapid emptying of a uterus for an incomplete abortion and he thought that the ether which was administered was not to blame.—Dr. Harold Low related a case of Acute Œdema of the Lungs following Gastrostomy.—Dr. Dudley Buxton then made some further observations on the remarks of the previous speakers.—The President regretted that the society had not had the benefit of the experiences of more of their surgical colleagues. He had only been able to find one case of pulmonary trouble in 900 cases of ether administration. The points which seemed to him to have been established by this discussion were: (1) that such cases certainly occurred; (2) the infrequency of their occurrence; (3) that the average age of the patients was lower than might have been expected; (4) that in the reported cases there was a marked preponderance of abdominal operations; and (5) the advantage of prophylactic measures. He quite agreed with Dr. Buxton's view as to the misleading character of the term "ether-pneumonia," for he was sure that the pulmonary troubles after ether did not in any way differ from those due to other causes.

Trustees: Dr. H. I. Fotherby and Mr. F. M. Corner. Honorary Librarian: Dr. T. H. Arnold Chaplin. Orator: Mr. John Poland. Secretaries: Mr. J. H. Targett and Dr. T. Glover Lyon. Council: Mr. H. L. Barnard, Mr. J. S. E. Cotman, Dr. W. A. Dingle, Dr. Fortescue Fox, Dr. E. W. Goodall, Dr. A. Butler Harris, Dr. W. H. Kelson, Dr. J. W. Oliver, Dr. W. Rawes, Dr. F. J. Smith, Dr. J. H. Sequeira, and Dr. T. G. Stevens. Auditors: Mr. F. Gordon Brown, Dr. Hope Grant, Dr. S. H. Appleford, and Dr. W. Rawes.

Reviews and Notices of Books.

A Text-book of the Practice of Medicine. By JAMES M. ANDERS, M.D., Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College, Philadelphia. Third edition, revised. London: Rebman, Limited. 1900. Illustrated. Pp. 1292. Price 36s. 2 vols.

THIS text-book is probably better known in America than in England, and the fact that it has reached a third edition is sufficient proof that the endeavours of the author to produce a useful work have been duly appreciated. The present issue, we are informed in the preface, is the result of careful and thorough revision. Especially was this deemed necessary as relating to the section on Infectious Diseases, a department in which the advance in our knowledge since the publication of the first edition has been considerable.

A special feature of the work will be noticed in the tabulation of the differential diagnosis. In the majority of instances this method has been carried out quite satisfactorily. In dealing with certain infectious diseases, however, the differential diagnosis can scarcely be considered complete. For instance, every practitioner must be familiar with the cases that are not unfrequently met with which at their onset look like influenza, but which afterwards prove to be typhoid fever. A diagnosis between these two diseases is often most difficult and its importance cannot be over-estimated, yet in considering the diagnosis of typhoid fever Dr. Anders does not even refer to influenza, and under the head of Influenza the possibility of mistaking the two diseases is dismissed in half-a-dozen lines.

Pneumonia and Acute Rheumatism are, as in most modern text-books, included under the Infectious Fevers, thus indicating that the author has fully brought the book into accord with scientific advances. In regard to acute rheumatism the author seems to have extraordinary ideas, for we find the following passage: "The disease [acute articular rheumatism] is, in numerous localities, endemic, and at times also epidemic; but, on the other hand, in not a few regions (especially European) is practically unknown—e.g., England, Belgium, and Russia." Further comment is needless. A few new subjects have been introduced in this edition—Glandular Fever, Ether-pneumonia, Splenic Anæmia, and Periodic Paralysis—whilst the accounts of numerous affections have been substantially re-written, such as the chapters on the Plague, Malta Fever, and Progressive Spinal Muscular Atrophy, whilst the descriptions of Typhoid Fever, Yellow Fever, Dengue, Arthritis Deformans, and the Diseases of the Circulatory System have been extensively revised.

LIBRARY TABLE.

Geburtshilfliches Taschenphantom. (*Obstetrical Pocket Phantom.*) One-third natural size. By Dr. ARTHUR MUELLER. Munich: J. F. Lehmann. 1899. Price 6 marks.—The phantom consists of an outline of a sagittal section of the pelvis in which the sacrum and symphysis pubis are represented by wooden blocks while the position of the soft parts is indicated by two watch-springs attached to the sacrum. Seven sagittal sections of the fœtal head corresponding to the form of the typically moulded head are supplied for use with the pelvis. By placing these within the pelvis the different positions of the head at the outlet and the movements of the soft parts can be to some extent represented. A model of a single blade of a pair of straight forceps is also provided and this can be fixed to the models of the head by means of pins and slots and used to demonstrate the application of the forceps at the outlet. In the letterpress supplied with the phantom the method of employing it is described, and a short account is given of the recognition, diagnosis, prognosis, and treatment of the various presentations of the head, together with a description of the method of applying the straight forceps at the outlet of the pelvis. The model is a somewhat ingenious one, but its utility is very limited since it is of no use for demonstrating the position of the head at either the inlet or in the cavity of the pelvis.

Who's Who at the War. London: Adam and Charles Black. 1900. Pp 72. Price 6*d.*—The enterprising publishers of "Who's Who" have issued a compilation from the larger publication, giving the names of various persons, officers and others, who are either serving at the war or engaged out there on some or other business. We notice that no information is given as to Sir Redvers Buller's school. He was, we believe, at Eton, and we understand that in the annotated school lists edited by Stapylton his name appears under the date 1856 as being in "Middle Division." It is possible, of course, that he may have been at Harrow too, as was claimed for him at the beginning of the war. The list of officers killed is sad reading; in all there are 212. The compilation is well up to date, taking in the battle of Spion Kop, but of course it does not give a complete list of all those in authority at the seat of war. On page 72 we notice that Major C. P. Walker, R.A.M.C., is mentioned as having been killed at Ladysmith. This is not correct, for Major Walker died from dysentery. In the list of wounded also the name of Lieutenant G. H. Goddard, R.A.M.C., is omitted. He was wounded near Paardeberg during the operations between Feb. 16th and 18th. However, the publication will be found useful. The biographical notices are reproduced from the larger "Who's Who." Mr. Cecil Rhodes is described as being fond of curios with "a preference for anything Dutch."

The Mirage of Two Buried Cities By JOHN FLETCHER HORNE, M.D. St. And., F.R.S. Edin. London: Hazell, Watson, and Viney, Limited. 1900. Pp. 341, and Index. Price 10*s.* 6*d.*—Pompeii and Herculaneum will for ever remain two cities of the most absorbing interest as veritable museums of a people whose life was suddenly cut short more than 1800 years ago. Dr. Horne evidently knows the district well and he says in his preface that the romance and poetry of his theme have charmed him and afforded him infinite pleasure. The book is in no sense a guide-book, but rather a series of essays written by an intelligent observer upon the bygone life of Herculaneum and Pompeii. There are plenty of persons who travel, especially that class whose only object is to "do" as much as possible in a certain time, who see indeed with the outward eye but who do not observe. Some persons do not want to observe; others do not know how to observe. It is for this latter class that Dr. Horne's book will be found a mine of wealth, and if they read it through they will find that the people who lived in Pompeii were in many ways very like ourselves. They will learn how they ate and drank and amused themselves; how they went to quacks and impostors of all kinds, both medical and religious; how there were among them heroes and saints as well as knaves and thieves. Anyone who has visited the buried cities will find pleasant recollections called up by this book and those who have yet to see them will find profit in reading it previously to a visit.

THE LANCET.

LONDON SATURDAY, MARCH 17, 1900

ON the evening of Friday, March 9th, the House of Commons decided by the significant figures of 124 to 34 to read for the second time the Bill for the Regulation of Midwives. Our Parliamentary correspondent gives in another column an explanation of the circumstances under which this sudden change in the fortunes of the Bill occurred. There was no effective resistance to the second reading, Mr. T. P. O'CONNOR'S well considered words pointing out that a large proportion of the medical profession were against the measure, and against it on general and social grounds failing to secure many adherents to the opposition camp. Dr. TANNER and Mr. AMBROSE supported Mr. O'CONNOR in his attempt to persuade the House that the proposed legislation contained serious perils to the community, but all statements to the effect that under the Bill an inferior order of medical practitioners would be created, with legal powers to exercise on the public that little knowledge which is proverbially so dangerous a thing were nullified by Mr. VICARY GIBBS'S sweeping and not completely accurate assertion that the General Medical Council, the Royal College of Physicians of London, and the Royal College of Surgeons of England were in favour of the measure. In a thin House badly informed upon the points at issue, the second reading was passed the whole proceedings upon the Bill, which included two divisions, only occupying three quarters of an hour. Several of the Members of Parliament who are also medical men were away from their places in the House but as the oldest parliamentarian could not have foreseen that the Bill would come up for second reading when it did their absence does not prove them apathetic.

What now remains to be done is for the medical profession to bring such influence as they possess to obtain modifications in the measure (1) whereby the general practice of midwifery in our country may not fall wholly or largely into the hands of a semi educated class, (2) whereby the scope of the licensed midwife shall be defined and (3) whereby encroachments upon medical practice and infringements of the Medical Acts may be obviated. We have reason to know from the answers which we received to our recent circular letter that while a great preponderance of professional opinion is against the measure, a very large number of medical men are so indifferent to a matter which concerns them vitally that they have never read the Bill. We strongly recommend them to read it now, and to read it in the light of the remarks which follow here. It is late but not entirely too late, for large alterations can be made in its provisions but they certainly will not be made unless the medical profession work hard and unitedly to obtain them. Under the Bill any woman who within two years from the date of the Bill becoming an Act claims to be certified under it, will be so certified provided that she holds a certificate in midwifery from the Royal College of Surgeons in Ireland or from the Obstetrical Society of London or such other certificate as may be approved by the Midwives Board. A similar claim may be made by any woman who can produce evidence satisfactory to the Board that on the passing of the Bill she has been in *bonâ fide* practice as a midwife and bears a good character. At the present moment, of the numerous women who practise midwifery no one denies that a large proportion are absolutely incompetent and that their bungling and malodorous ministrations constitute a source of the gravest danger to the parturient poor. Those who desire an Act of Parliament to regulate the practice of midwives proclaim these facts loudly and see in them the chief argument for the necessity of licensing the handmaids of obstetric medicine after ensuring to them a minimum of properly directed training. Those who are opposed to such regulation equally dwell upon the terrible stories of malpraxis that have been again and again told in coroners courts and in these columns, and in so doing maintain that the dangers will be largely increased under the intended legislation, inasmuch as a grade of practitioners will be created by it who will remain for medical intents and purposes uneducated, even while Government confers upon them the outward and visible signs of obstetric knowledge. The Board will have to decide which of these women are and which are not in *bonâ fide* practice and which are and which are not up to the Board's standard of knowledge—whatever that may be. This Board, which at the outset of its work will be confronted with such exceedingly delicate questions, is according to the Bill to be composed of four registered medical practitioners chosen respectively by the Royal College of Surgeons of England, the Royal College of Physicians of London, the Society of Apothecaries of London, and the Incorporated Midwives Institute, of two persons, one to be a woman, appointed by the Privy Council, and of one person to be appointed for a term of three years by the Association of County Councils. There is nothing to prevent the last three persons being medical practitioners, while the first four will possess medical qualifications. A majority of medical opinion is therefore assured on the Board so that it is to be hoped that in the matter of deciding how the first midwives' roll shall be formed sound counsels will prevail. In carrying out the great duty that will be confided to the Board of regulating, supervising, and restricting within due limits the practice of midwifery, it will be perfectly impossible for the Board to lay down any definite rules to guide their action which will remain exempt from criticism. The due limits of the midwife's work in an ideal condition of things would keep her to nursing and nothing but nursing including the first care of the infant if healthy. In such an ideal condition of things the whole province of obstetric medicine belongs to the fully qualified medical practitioner, for it is obvious that no one can say that at one particular place or another a case passes from physiology to pathology. There being no natural point of division the Board will have to devise some artificial rules saying clearly to the nurse. Thus far shalt thou go and no further"; and, in spite of the valuable fact that medical knowledge will guide and influence the Board, they will find their task a very hard one, and must not hope to escape severe judgment whatever they do. For they are committed to illogical courses by the Bill.

We publish in another column the names of the Members of Parliament who voted for the second reading of the Midwives Bill. Medical men residing in the constituencies represented by these gentlemen may write to them, if they have not done so already, and indicate what are the objections taken by the medical profession to the measure, and he same course may be followed by all of our readers who desire to influence, however late, the shaping of the Bill. They may in this way effect something, although not a tithe of what would have been accomplished if legislators had been placed individually in possession of individual medical opinion from the commencement. Moreover, it must be remembered that the Bill has been referred to the Standing Committee on Law, which is a more expeditious proceeding than reference to a Committee of the whole House The lines on which the measure requires modification have been clearly laid down in our columns at different times, and our readers must remember in addressing their Parliamentary representatives to insist upon the public harm that may accrue from the passing of the present Bill for the regulation of the practice of midwives. The support which this Bill has already received must not be minimised, and Dr. RENTOUL's threat contained in his otherwise able and suggestive letter on page 805 that "should the Bill become law every honest practitioner will spurn and treat it with contempt and refuse to recognise it" should certainly not be made. Honest men do not refuse to obey the law, but a good citizen tries to play his part in bringing the law into line with his convictions of what is right. The General Medical Council and the ruling bodies of the Royal College of Physicians of London and the Royal College of Surgeons of England are in favour of the principle of the Bill. Such supporters have gained for the Bill its second reading, and the point to be insisted on, in urging modifications of the measure, is that the opinion of these groups of gentlemen is not the opinion of the medical profession at large. The General Medical Council does not represent the views of the medical profession any more than the ruling bodies of the English medical corporations represent the views of their members. Again, while no one can be certain how far the Bill in all its details satisfies the officials of the corporations, we can see one place where it fails distinctly to meet the views of the General Medical Council. It does not make the provision advised by the Council "requiring the licensed midwife to apply for qualified medical assistance in every case attended by a midwife which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new-born child." This provision is in the opinion of the Executive Committee of the General Medical Council an imperative necessity, and the Council cannot be claimed as supporters of the Bill while no such clause is contained in it.

Until our circular letter was issued to the medical profession of England no one knew exactly what the professional feeling was on the matter. Each side was given to pooh-poohing the standpoint of the other; the conduct of the promoters of the Bill was called unprofessional if not illegal; that of its opponents was called selfish; and in each case we were assured that the leading part was being played by an insignificant if noisy minority. Those of us who were in a position to know could have predicted what the result of the canvass would be fairly closely, but there would have been nothing to prove, without the canvass, that the prediction was more accurate than the factious remarks of the extreme partisans. Medical men can now ask for modifications of the measure on the excellent ground that four-fifths of their colleagues join them in believing that it is, as it now stands, an infringement of the Medical Acts, which Acts were designed to protect the public against irregular medical practice.

IT is pleasant to notice how much the munificence of one man may serve to elevate the whole conception of generosity. The actual money gift bequeathed to four London hospitals by the late Professor DAVID EDWARD HUGHES is a substantial addition to our means of dealing with the suffering of the sick poor of the metropolis. And we cannot but admire the excellent choice of hospitals which was made by the deceased benefactor. But especially the will is exemplary, as that of a scientific man taking no fantastic or faddy views of the merits of hospitals, but looking at them as institutions which contemplate alike the relief of patients within their walls, the perfection of medical science, and such instruction of students in the medical art as shall ensure the wide diffusion of medical knowledge and skill. The censorious criticism by narrow or hypersensitive persons of our great hospitals is a somewhat deplorable feature of recent times, and is well rebuked by such wills as that of Professor HUGHES whose scientific mind gives value to his judgment.
